SURGEON, CHILDREN'S HOSPITAL, BRISTOL, SENIOR ASSISTANT SURGEON, BRISTOL ROYAL INFIRMARY

(With Special Plate)

For several decades occasional observers have reported cases of simple dilatations of the oesophagus resembling adventitious stomachs, but they are only now becoming readily recognized For this recent facility in diagnosis we have to thank Roentgen Radiography, after the ingestion of an opaque meal, makes the diagnosis of such

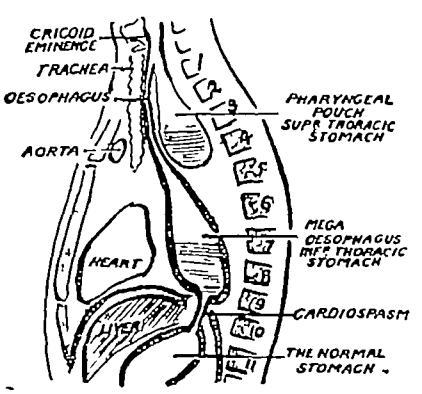

FIG A.—Showing upper and lower thoracic stomachs in profile in the chest

intrathoracic enlargements one of easy and convincing clarity instead of recondite conjecture, as when the doctor depends wholly on clinical acumen

These expansions are found at the upper and lower ends of the gullet In shape and in their relationship to the parent gullet they resemble aneurysms, such as occur in the adjacent aorta The upper is saccular and the lower fusiform in outline A diagram of them in profile indicates their deep dwellings in the chest—and the reason for the picturesque title of these remarks (Fig A) As a matter of fact, the title is not an abuse of the word 'stomach," but a reversion to its proper use, for 'stomach" is derived from the Greek word meaning gullet" and Galen, among other anatomists, preferred the name ventricle" for the subdiaphragmatic stomach They are familiar as "pharyngeal pouch" or "diverticulum," the lower one occurring in the condition known as cardiospasm Diaphragmatic hernia of the normal stomach into the thorax is not included in this paper

It is hoped that reasons other than the mere infrequency and pathological curiosity of these conditions will make this communication helpful A doctor's duty to his patients makes it necessary to recall these disorders to mind from time to time Their remoteness in the hidden depths of the chest hides them from simple view, and the old saying still holds good—"Out of sight, out of mind" While failure to recognize some lesions makes little practical difference to the patient, this is not true in the case of thoracic stomachs They disable the victim, progressively and gravely, if left to nature, but, despite their inaccessibility, they are amenable to sure relief by surgery Reports on such cases, rare but vital, keep the doctor on the look out for them

A few notes of illustrative cases will serve as a basis for consideration of the clinical features of these alimentary pouches

Case I

W H C, aged 62, was a monumental mason, but had only been a supervisor for the last fifteen years He came to me in August, 1929 His past health had been good He stated that for ten years queer audible noises occurred during swallowing Three years ago vomiting—as from a pump—started and brought relief For nine months there had been increasing dysphagia and vomiting This was lately so severe that life had become unbearable he was rapidly losing weight, and had increasing constipation for five months He sought urgent relief in order to nourish himself He had been disposed to heart attacks, having fainted three times in the street, and he had swelling of the feet

On examination he was somewhat pale and spare in flesh His teeth were offensive There was no swelling in his neck, but there was a feeling of food stoppage behind the upper ribs A vomit of six ounces by his bed looked like creamy tomato soup It was acid to litmus, due to decomposition, not, presumably, to admixture with gastric juices, and inoffensive in odour Vomiting occurred within at the most, a few minutes of ingestion Pharyngoscopy by Mr Angell James revealed the walls of the pouch, but no exit

He was radiographed after the ingestion of an opaque meal, when the barium was seen to occupy a substernal pouch the shape of half a small orange, with the flat surface upwards (Figs 1 and 2) It was median, with a slight bulge to the right and its smooth, convex lower aspect was at the level of the fourth dorsal vertebra

Similar cases reported in the literature occur mostly in patients of the fifth decade, and are of several years' duration Sensations of strangling and of troublesome coughing on recumbency are noted, as well as regurgitation of food on pressure of the left side of the neck The patient referred to above showed diminished nutrition, for thoracic stomachs, unlike their abdominal congener, boast no digestive attributes, but rather impede the process

Operative Treatment

Following the method used by Wilkie[1] diverticulectomy was commenced on September 4th 1929 and the second stage of the operation was completed on the 18th The pouch was exposed by an incision along the anterior border of the left sterno-mastoid muscle between the thyroid gland and larynx medially and the carotid sheath laterally Resting on the prevertebral muscles was a smooth bluish yellow flappy membranous structure It was like a thick walled hernial sac di closing boundaries and coming to resemble a bag as it was gently dissected free of the vertebrae at the back and the viscera in front The recurrent laryngeal ner e was guarded To help to define the neck of the sac at this stage an oesophageal bougie was passed by Dr Stock with ease demonstrating the absence of stricture Here and there a few vessels coursed over the sac and were ligated but bleeding was not troublesome The sac was pulled on to the neck and maintained there by stitching it to the skin margins (Fig 3) The patient swallowed solids joyfully after this operation and suffered only mild cellulitis The second stage consisted in dis section of the pouch to its neck which was ligated the fundus was cut off and the stump cauterized

The patient was able to eat anything after this and returned home and was about for a short time During this period the neck healed soundly He then had an attack of influenza followed by pyrexia and died in four months When he was radiographed in November an opaque meal dropped straight to his stomach no trace remained in his neck Professor Nixon saw him on November 12th and stated that his poor health had nothing to do with the operation

A rival procedure for diverticulectomy is diverticulopexy —that is, fixation of the inverted sac—so successfully carried out by Hill in a series of fifty ca es

Before studying the nature and cause of the upper thoracic stomach a few notes on two examples of the lower thoracic stomach of cardiospasm will be given

CASE II

W S a man aged 50 complained of dysphagia of only two years duration His past history included four years in the trenches in the late war and was good apart from a tendency to a winter cough He felt food arrested on a level with the sternum and usually vomited his food after taking it Cough aggravated the condition Fluids were swallowed better than solids He was a big man and had lost much weight His teeth were carious but he had a fair colour Nothing abnormal was found except that auscultation revealed an interval of ten seconds between swallowing a drink and the entry of the fluid into the stomach. An opaque meal showed a fu iform swelling of the lower oesophagus (Fig 4) A diagnosis of cardiospasm was made

Operative Treatment

Mikulicz s method recently revived by Walton was followed Walton gives a timely warning on the need for lavage and empty ing of the stagnant oesophagus prior to operation The stomach was opened and the index finger pa sed into the contracted cardiac orifice The remaining digits were also introduced one by one till the resistance yielded Thereafter he was able to swallow any kind of food he put on weight and worked In April this year the symptoms recurred in association with bronchial trouble and he vomits if he takes his food too quickly Radiograph- revealed food pa sing undelayed through the lower oesophagus A mercury bougie was used for the relief of his symptoms and a radiogram shows it *in situ* (Fig 5)

CASE III

F aged 48 whose trouble started gradually in 1924 with an occasional meal causing a block in the gullet had a good past history apart from nervous debility in 1912–14 He was specially affected by greasy foods and cold liquids Severe retrosternal pain often rising to a crisis disappeared when his food passed a certain part leaving him exhausted On the morning after he often vomited unaltered the food he had eaten the day before Blood was never present His radiogram after an opaque meal is reproduced as typical (Fig 6) It shows a large lower thoracic stomach with its epiphrenic contour characteristically smooth. The fine oblique trickle of barium that alone escapes into the stomach is a constant feature of these cases It is notable that the con striction is a tunnel about 1 inch long and not a mere ring at the cardiac orifice It corresponds to the normal so-called cardiac sphincter of the oesophagus (Hurst)[4] where that tube passes through the diaphragm This appearance led Chevalier Jackson to apply the term phrenospasm in preference to cardio-spasm With such a picture and history endo copy seems as superfluous as with the one illustrating pharyngeal pouch

Operative Treatment

As in the former case Mikulicz s digital dilatation was adopted and the fingers were introduced up to the proximal interphalangeal joints as advised by Walton Convalescence was smooth except for a slight mucoid discharge from an upper stitch hole which lasted a few weeks and was possibly caused by a slight leakage from the gastrotomy He is a stone heavier and is still very pleased to swallow normally not having had a decent meal for years prior to the operation

The best alternative treatment is the use of mercury bougies of increasing diameter as prescribed by Hurst but for inveterate case, such as the above. I am in favour of Mikulicz s measure, so ably endorsed by the clinical practice of Walton[2]

Dilatation with the hydrostatic bag of Plummer[3] open to the grave objection that during its use accidental rupture of the oesophagus can be less easily guarded against than with digital dilatation and if rupture occurs it cannot be repaired at the time as in the open method

In the diagnosis of these maladies a detailed description of symptomatology is no longer necessary since the radiogram taken routinely in dysphagia reveals a shadow characteristic both in site and in level Thus it readily distinguishes the mild transient oesophageal spasm of functional troubles thoracic aneurysm, and other mediastinal swellings With the comparatively rapid formation of cancerous obstruction in the oesophagus little dilatation develops and with this type of stricture the lower end of the barium column is uneven where it rests on the cancer

NATURE AND ETIOLOGY

A comparative study of the upper and lower types of thoracic stomach reveals more about both than when each is considered separately Common to both is this important feature—namely, that the site of origin of each corresponds with a transition stage in alimentary transport At the upper end is the change over from voluntary to automatic action, and at the lower from the simple tubular oesophagus to the specialized function *of the normal stomach*

It is notable, on examining the structure of their wall that the epiphrenic stomach consists of the hypertrophied muscular coats of the oesophagus and shows all the normal characteristics of muscular tube- proximal to an obstruction while the pharyngeal pouch is merely a mucosal hernia with a thin areolar investment which hangs as a blind bag at the back of the main alimentary tube For the lower stomach, dilatation of the oesophageal exit through the diaphragm is needed and adequate in the upper part but *there is no constriction of the normal pattern* nor would there were, could it dilatation remove the power that lung outside the tube The e differences arise from the different structures and mechanisms of the entry and exit of the gullet During deglutition the food bolus is quickly conveyed from the mouth into the pharyngeal funnel The longitudinal muscles—for example the stylo-pharyngeus and the palato-pharyngeus—then raise this funnel at its upper end and circular contraction squeezes the bolus into the narrower hypopharynx Here the bolus is handed over to the involuntary peristalsis of the gullet It is a region of stress and also of inherent weakness The signs of the cricoid ring forms a projecting hump anteriorly (Fig 4) while the rest of the circumference is encircled by the crico-pharyngeal portion of that compound muscle known as the inferior constrictor Little longitudinal support is present and the osseo-muscular ring above described recesses the assault of the bolus descending into its smaller circumference from the roomier upper pharynx It is a segment of strain owing to the narrowing lumen and to transition from voluntary to automatic transport of food The subtle mechanism of adjustment may easily be thrown out of gear Oral sepsis pharyngitis and oesophagitis or even subphrenic ulceration, may raise the sensibility of the part and so set up protective hypertonus at the oesophageal doorway Just outside the resistant door lies the inherently weak posterior area of the pharyngeal wall (Negus[5]) between the crico-pharyngeal and thyro-pharyngeal elements of the inferior constrictor No actual congenital pouch exists When the crico-pharyngeus fails to relax smoothly the pent-up impetus presses on the *posterior pharyngeal wall, and the weak area yields The* bulge is directed down behind the oesophagus by gravity and mutual pressure of the thyroid gland and the bulkier

pharynx above When large enough a descending bolus will drop more readily into it than into the mouth of the oesophagus, which is displaced forwards and comes to look backwards The oesophageal orifice is like the slit of a letter-box, past which the descending bolus readily drops, and falls instead into the open mouth of the pouch below (Fig B) They are shown respectively as X and Y in the diagram

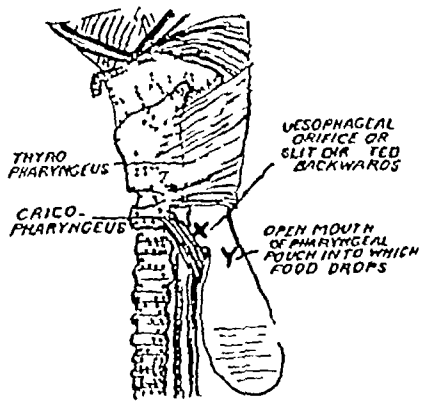

Fig B—Diagram showing pharyngeal pouch as a mucosal hernia

That the diversion of the food is not caused by stricture of the oesophagus is proved, as in the case of W H C, by the immediate ease with which food passes as soon as the pouch is elevated from the thorax by operation and pulled out on the neck The relation of X and Y is simply reversed by this manœuvre, and the orifice of the pouch now presents a narrow slit on the side of the pharyngeal wall, while the mouth below leads straight down the red lane to the stomach (Fig C) Hence the rationale of the operations previously mentioned

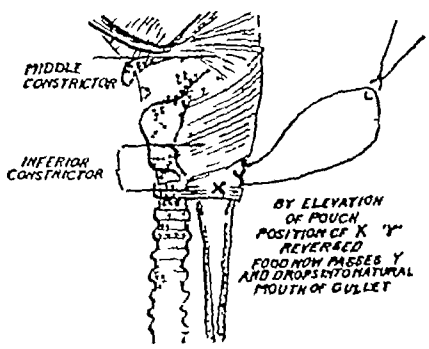

Fig C—Diagram showing rationale on which diverticulectomy and diverticulopexy are based

Development of the Lower Thoracic Stomach

Just above the oesophageal exit arises the epiphrenic stomach involving, to varying heights, the lumen of the gullet above Below the dilatation the lumen of the terminal inch of the gullet, when examined radiographically or by the sense of touch at operation, is but a tiny tunnel through which only a trickle of barium escapes Valuable necropsies, such as that of Morley[7] on such a case, confirm the truth of this, and establish the absence of muscular hypertrophy at the constriction

Numerous causes for this shrunken calibre have been advanced Among them a defect in the neuro-muscular mechanism from birth has been suggested, but it is hard to attribute to a congenital cause a disease first manifesting itself in maturity Walton[8] supports this view, citing rare cases that have occurred in the early years of life He regards the phenomenon as parallel with the faulty co-ordination of neuro-muscular mechanism responsible for the megacolon of Hirschsprung's disease and infantile dilatation of the urinary system, which occur without mechanical blocks Harold Brunn[8] supports the theory, and explains the late onset of the condition by the analogous latent period in cases of cervical rib

The opinion of Mikulicz, to whom we owe the cure by digital dilatation, is expressed by the historic title given to the disease by him—namely, "cardiospasm" That spasm is a potent element in these cases, at least in the earlier stages, is evident from the sudden relief of obstruction, onward passage of food, and relief of pain observed in my case (V F) and in so many of the histories reported

Plummer, after his vast experience, supports the neurogenic theory If accepted, the condition falls into line with that of congenital pyloric stenosis, but in that, if there is overaction of the muscle, it is certainly accompanied by hypertrophy However, it is open to question whether an accommodative diminution in the size of the muscular opening in the diaphragm occurs *pari passu* with the diminished calibre of the gullet, and so inhibits the expected hyperplasia

Hurst[4] remarks on the easy passage of the gentle mercury bougie, and affirms that there can be no positive spasm but mere non-relaxation of the sphincter ("achalasia") Thus he attributes to degeneration of Auerbach's plexus, and has seen this in sections from such cases If the theory is accepted, it involves the belief in some peculiar susceptibility of this segment of the alimentary tract to a poison apparently impotent elsewhere, for there is actual hypertrophy of the circular muscle immediately above the constriction Certainly, in the inveterate case on which I operated, resistance was inelastic and caused by organic contracture This may well be the late outcome of achalasia of the incipient stages by accommodative contracture of the surrounding tissues and the fibrosis following chronic congestion induced by the superincumbent pseudo-stomach

Soper and Cassidy[9] found, in 29 out of 60 cases, pathological lesions elsewhere—for example, gastro duodenal ulcers, gall-stones, pleural contractures, and exophthalmic goitre The last were improved by dilatation of the gullet In my patient (W S) associated bronchial catarrh is noted This conjunction affords a source for possible reflex dysfunctions of the cardiac sphincter Greenwood,[10] from his own case, forcibly argues that dysfunction is due to imprudent feeding when hurried, unmasticated meals provoke irritability and hypertonus of the stomach inlet

The title "phrenospasm" (Chevalier Jackson) lays the blame on the encircling diaphragm Two criticisms of this explanation are suggested The grip of a thin sheet of muscle would make a narrow groove on the gullet, but the findings are those of a tunnel obstruction an inch or more long Morley remarks that phrenicotomy fails to relieve the impasse

Finally, in the cadaver, I am impressed with the resistance offered by the half-encircling edge of the liver when passing a finger into the oesophagus Clark[11] refers to this relationship It is not, in my opinion, an adequate etiological factor, or signs of an impeded cardiac orifice would be manifested more often in conditions of hepatomegaly

The theories mentioned broadly encourage the belief that there is defective neuro-muscular action at the oesophageal exit, but whether this is inherited, brought on by the irritation of imprudent feeding, reflex from distant foci of disease, or the result of local neural degeneration, further research must prove

Summary

It is very probable that a neuro-muscular dysfunction at susceptible transition points in the gullet raises the pressure of ingesta This effect expresses itself by different forms of dilatations The inherent weakness in the posterior aspect of the hypopharynx produces a hernia of the mucosa By contrast, in the epiphrenic region, the oesophageal walls respond to the hypertension within by a typical uniform dilatation and hypertrophy From such origins spring the substernal and epiphrenic stomachs They are likely to continue to vex the human race, evoke the discernment of the doctor, elude prophylaxis, and require most skilful surgery to relieve them

In pharyngeal pouch two-stage diverticulectomy is the best remedy, while cardiospasm, in the early stages, will respond to merp dilatation with bougies, which is best done with the aid of the radiographic screen Where this fails,

Mikulicz's digital dilatation by means of a gastrotomy, is necessary and effective By reason of the comparative infrequency of these conditions, their deep situation, and the vital structures around them, their treatment calls for special care and skill

I am indebted to Dr F J Maves for all the radiological work contributed to the diagnosis of my cases

TWO CASES OF BONE TUMOUR FROM ANCIENT EGYPT

BY

R A GARDNER, B Sc, M B, Ch M, D M R E,
DIRECTOR RADIOLOGICAL DEPARTMENT

AND

A L URQUHART, O B E, M B, D P H,
PROFESSOR OF PATHOLOGY
(Departments of Pathology and Radiology Faculty of Medicine Egyptian University Cairo)

(*With Special Plate*)

[T]ure of the diseases which were present among Egyptians but little is known Such specimens have been found and examined have been generally from the Roman period of occupation, which is, relatively speaking, late in the history of Egypt Pathological specimens have been obtained from the predynastic periods

So far described are mostly associated with the non-resistant portions of the body—namely, the bony tissues—as these parts, unless some form of mummification is undertaken, best resist the destructive influence of time and climatic conditions There have thus been preserved for us specimens which enable us to diagnose conditions which were then associated with the osseous system of the body The supply of these interesting specimens, which reach us only too rarely is mostly derived from the archaeologists, who in the course of their work observe abnormalities in the occupants of the graves and tombs which are being investigated from the archaeological point of view To them, therefore, our thanks are due for the interest they take in this side issue of their work We have to thank Mr Guy Brunton for both the specimens described in these notes

Osteosarcoma of the Femur

The first of these specimens, that of a tumour of the femur, was found by Mr Brunton in a grave at Mostagedda, south of Assiut, on the eastern side of the Nile, on the edge of the desert The specimen belongs to the Ptolemaic period

The bone is the right femur of a young person the head of the bone and the trochanteric epiphyses have not become united and are therefore absent The photograph in the centre of the illustration (Fig 1) gives a good impression of the condition of the bone, the neck of the femur is seen at the upper end of the specimen The bone itself is 10 in long and the surrounding bony growth involves the greater part of it The growth at its [illegible] part is 3½ in in diameter In the fresh state the growth would have been considerably larger because the delicate spicules of bone which form the osseous portion of the tumour are in large part broken off, while time and wear have produced a relatively smooth surface on the mass The soft parts of the tumour have completely disappeared In certain areas, however, the typical bone picule formation of osteosarcoma is evident while the skiagram on the left of the photograph in the illustration shows the typical architecture of the growth The skiagram is obviously that of a long bone of which the cortex while rarefied is unbroken and unchanged in width The medullary space shows no expansion

Extending outwards in a direction at right angles to the shaft are shadows arranged in the form of parallel striae It will be observed that the extent is largest about the mid-point of the bone We should suggest from the radiographic appearance it is a justifiable inference that a bone-forming sarcoma has originated about the mid point of the femur One can therefore definitely exclude such a condition as chronic osteomyelitis which might perhaps be suggested by the gross naked-eye appearance of the specimen

For comparison, a skiagram of a similar osteosarcoma of the humerus, occurring in a young Egyptian patient (Kasr-el-Aini Hospital in patient No 449 of 1930) is reproduced If allowance is made for the fact that in this skiagram the soft parts are shown, the similarity between it and the skiagram of the Ptolemaic bone is evident We therefore venture to diagnose this tumour of the Ptolemaic period as an osteosarcoma and infer that some 2,000 years ago this type of malignant growth was already present in the population of Egypt

A search of the literature for records of similar cases shows that Ruffer,[1] in his "Studies in palaeopathology described a tumour of the pelvis (dating from the Roman period) found in the catacombs of Kom-el-Shoogafa in Alexandria He observed that this tumour had expanded the iliac bone and consisted of a solid bony tumour containing cyst-like spaces Although he suggests that it may be an osteosarcoma from which all soft parts have disappeared it seems more probable to us, from the illustration, that it is an ossifying chondroma

Tumour of the Mandible

The second specimen also sent to us by Mr Brunton, was found by him in the same district in a grave of the pre-dynastic period In all probability therefore its age is not less than 5 500 years This tumour presumably is one of the earliest if not the earliest, yet found amongst the former dwellers in the Nile Valley

The tumour occurs in the left side of the mandible and involves portions of both the horizontal and ascending rami It extends from the region of the canine tooth to the angle of the jaw the bone of which is expanded and reduced to a shell The soft parts of the tumour have disappeared, leaving the cavity in which it lay widely open at the alveolar surface This cavity is 3½ in in length and 3/4 in in depth, while the widest diameter is 1¼ in From the floor of the cavity, and projecting from its sides the remnants of some bony septa can still be seen The teeth and soft parts are absent The illustration (Fig 2) shows on the left side a photograph and on the right side a skiagram of the condition In the latter may be seen the widening and thinning of the bone while the cortex along the inferior border of the mandible is intact For the production of the skiagram the rays were directed relatively to the bone at approximately the same angle as would be employed in the living subject

The diagnosis of this condition cannot be definitely established but the possibilities of a round cell sarcoma, a dentigerous cyst a simple cyst or a fibroma should be considered of these the former appears to be the most probable

SPONTANEOUS SUBARACHNOID HAEMORRHAGE, WITH KORSAKOFF'S PSYCHOSIS

BY

A W CUBITT, B M, B CH,

LATE HOUSE PHYSICIAN, KING'S COLLEGE HOSPITAL

IN the *British Medical Journal* of June 8th 1929 Professor Arthur J Hall described two cases of subarachnoid haemorrhage which developed Korsakoff's psychosis The following case seems worth recording The patient had recurrent haemorrhages and from each succeeding haemorrhage the recovery was less complete He developed Korsakoff's psychosis, and finally died seven days after the first haemorrhage The diagnosis was confirmed at autopsy

Clinical History

The patient was a man aged 57 an old soldier tall and strongly built apparently in perfect health with no history of any illness of importance On July 29th he was rather unwell, complaining of headache, he vomited once, but recovered The next evening he went to a whist drive during which he suddenly collapsed on the floor When first seen about an hour later he was very restless, throwing his arms and legs about, trying ineffectively to get up and to untie his hands He made apt but rather curious statements, such as "I'm badly handicapped" He did not answer questions or seem to be aware of his surroundings He was moving the left side of the body more than the right The left pupil was rather large, the right small and less active to light The knee jerks were brisk, the right less so than the left Both plantar reflexes were flexor *The heart appeared normal and the arteries did* not seem to be thickened The urine contained a trace of albumin During the next hour or two he became quieter and somewhat more rational and answered questions A diagnosis of subarachnoid haemorrhage was made

By next morning the pulse rate had gradually fallen to 58, he was becoming more and more comatose, the respiration was of the Cheyne Stokes type The blood pressure was 90/45 He was still moving his limbs but very slightly The knee jerks had become exaggerated, there was double ankle clonus and double extensor plantar response *Lumbar puncture* was performed, the fluid was under considerable pressure, and blood stained throughout Directly after the lumbar puncture the exaggerated knee jerks, ankle clonus, and extensor response disappeared The blood pressure rose to 110/75, and the breathing became regular, but the pulse remained at 58 The left optic disc showed no papilloedema, the right disc was not seen on account of the contracted pupil Four and a half hours after the lumbar puncture he became conscious, asked where he was, and said he would like some whisky He was *fairly quiet through the night, took fluids, and passed water* spontaneously

Examination of the cerebro spinal fluid showed

Red blood corpuscles	131 600 per c mm
White blood corpuscles	395 per c mm
Lymphocytes	320 per c mm
Polymorphs	76 per c mm
Total protein	1 000 mg per 100 c cm
Globulin	++
Chlorides	740 mg per 1 000 c cm
Sugar	Normal
Van den Bergh reaction	Delayed reaction 0 2 units
Wass mann reaction	Negative
Lange s colloidal gold test	0000023211

Next day, August 1st, he showed a definite Korsakoff psychosis There was complete disorientation as to place and time fairly good memory for past events, but fabrication of recent occurrences *In the evening the pulse began to fall* Lumbar puncture was again performed and blood stained fluid under pressure was withdrawn The fluid rapidly became more blood-stained, he complained of headache, then suddenly began to breathe stertorously while clonic movements of the hands and arms took place The needle was quickly withdrawn The patient was cold and sweating, the pulse very feeble, and double ankle clonus and extensor response were again present The left pupil contracted, so that it was now equal to the right The pulse and respiration gradually improved He *became very restless and destructive* He answered questions with Yes and No and obeyed orders for a few seconds, but soon began to try to dismember his bed again He remained in this condition all night The pulse was full and slow, sometimes falling to 40 The left pupil had dilated, and the ankle clonus and extensor response disappeared

Next day Korsakoff's psychosis was well marked His mind seemed to run on his army days On being asked what he was doing when he appeared to be reaching for something, he replied, "Collecting items" "Items of what?" "Stores" He was very suggestible, and was led into saying that he had been out for a walk that morning, and had met the Archbishop of Canterbury, who asked him how things were going

At 11 p m he suddenly *became comatose*, with stertorous breathing There was no apparent cause for this renewed haemorrhage The breathing became very slow, consisting of deep gasps, which occurred every fifteen to twenty five seconds The pulse remained fairly good The left pupil again contracted, and ankle clonus and extensor responses appeared both were more marked on the left side He vomited through his nose and for a time there was a good deal of rattling in the throat There was a left divergent squint for a short time, followed later by conjugate deviation to the left About 12 30 a m *he became very rigid the legs extended* and the back arched An anaesthetic was given to relax the extensor muscles of the back, and lumbar puncture was performed, 40 c cm of blood stained fluid was withdrawn slowly, it was under considerable pressure The breathing and pulse improved, and the rigidity did not recur

Next morning, August 3rd, the coma was still deep Respiration was quiet the pupils were equally contracted, there was no squint or conjugate deviation, there was marked blepharospasm The right optic disc showed papilloedema, the left disc was not clearly seen *The blood pressure* was 135/90 The temperature, which had remained subnormal, rose to 100 6 and the pulse rose from 48 to 88 There was still a trace of albumin in the urine There were a few rales at the bases of the lungs The respiration rate was 24

In view of the fact that lumbar puncture failed to relieve the coma it was decided that decompression was justifiable At 3 30 p m a right subtemporal decompression was performed, the dura mater was a little thickened there was a layer of blood under the arachnoid membrane, and the brain bulged out somewhat At the *end of the operation the respiration and* pulse were improved The coma however, continued unchanged About midnight the respiration rate began to rise and next morning reached 60 Signs of broncho pneumonia developed, the patient became cyanosed, and died at 9 30 p m on August 4th

Post mortem Examination

The brain weighed 2 lb 2½ oz The dura mater was thickened The arachnoid was also thickened especially over the right parietal region Blood was diffused all over the surface of the brain between the arachnoid and the pia mater, when the pia arachnoid was stripped off the brain the convolutions were seen to be a little flattened the brain substance was *not* congested, and there were no haemorrhages *into it* There was a large clot of blood at the base of the brain in the region of the circle of Willis around the medulla and pons, between the medulla and cerebellum, and in the right Sylvian fissure The circle of Willis and its branches showed a considerable amount of thickening, there was one fusiform aneurysm, and one small, thin walled saccular aneurysm containing clot, this was possibly the site of the haemorrhage The fluid in the lateral ventricles was slightly stained with blood, in the wall of the anterior horn of the left lateral ventricle there was a small, yellowish, softened area

Microscopical section of the brain substance showed no abnormality Branches of the circle of Willis showed considerable patchy proliferation of the intima, which in many places was thickly infiltrated in its outer layers with round cells There was no marked thickening or splitting of the elastic laminae The media was not thickened, but there were areas of round-celled infiltration, which was also well marked in the adventitia

The heart was large, weighing 17½ oz There were some fatty patches under the endocardium, especially at the bases of the papillary muscles The mitral and tricuspid valves were a little thickened The condition of the coronary arteries was surprisingly good, and the aorta was unusually free from atheroma

The lungs were congested and oedematous In the left lower lobe there were patches of broncho pneumonia and pus could be squeezed out of the small bronchi The left kidney showed a depressed area resembling an old infarct The cortex of both was a little diminished, and the surface slightly granular To the naked eye there was no evidence of arterio sclerosis Microscopical sections showed patchy areas of fibrosis, with *atrophy of the epithelium of the tubules, there was very little* cellular infiltration, many of the arterioles showed marked reduction or even obliteration, of their lumen, due to proliferation of the intima, with no cuffing with lymphocytes Other parts of the kidneys showed no interstitial change, but some cloudy swelling of the tubular epithelium

The evidence is not sufficient to justify a certain diagnosis, but in spite of the negative Wassermann reaction and the undoubted arterio-sclerotic changes in the kidneys it seems probable that the changes in the membranes and vessels of the brain were due to syphilis, and that the

haemorrhage was due to the rupture of a small aneurism of syphilitic origin on one of the branches of the circle of Willis

The sudden appearance of pupillary and pyramidal tract signs with each fresh haemorrhage, and their rapid disappearance after the relief of pressure by lumbar puncture, was an interesting feature of the case

I have to thank Dr T L Livingstone and Mr J B Hunter for their permission to record this case

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

RUPTURED LIVER SUTURE

RUPTURE of the liver does not commonly come to operation, as in the first place it is not very frequently seen, and in the second place when it does occur it is either so severe and complicated by other injuries as to be rapidly fatal, or else it is a small subcapsular tear not requiring operative intervention An interesting point about the case reported below was the interval between the accident and the onset of abdominal pain during which the patient felt comparatively well There was also surprisingly little shock *consequent on such a severe injury*

A builder aged 30 was admitted to hospital on March 9th after a cycling accident in which he had a head-on collision with a car He was struck in the abdomen (he thought by the mudguard of the car) and immediately afterwards got up unaided and felt no pain Ten minutes later however he was seized with severe abdominal pain unaccompanied by faintness nausea or vomiting

On admission the pulse was 64 temperature normal and there were no signs of shock there was some rigidity and tenderness in the right upper quadrant of the abdomen The patient had vomited once since the accident The pulse proceeded to rise slowly but steadily and rupture of the liver was diagnosed When I saw him twenty four hours after the accident the pulse was 100 rigidity and tenderness on the right side were marked there were no signs of free fluid in the abdomen but the patient looked strained and was still complaining of pain

Laparotomy was performed through a right paramedian incision enlarged by transverse division of the right rectus There was a considerable amount of free blood in the peritoneum and a rent was found in the right lobe of the liver extending from the edge for four inches on the upper surface and six inches on the lower steadily oozing blood The tear was very difficult to get at being in the posterior axillary line but six or seven interrupted catgut stitches were inserted bringing the edges into apposition No other visceral injuries were present The wound was closed in the usual manner Nine days later a biliary fistula appeared and persisted for four weeks but ultimately healed and the man was discharged fit

I am indebted to the staff of the Farnham Infirmary for the opportunity to operate on this case

A PATHOLOGICAL MONOCYTE

THE leucoblast was described by Pappenheim as being a large cell, with a nucleus resembling that of a myelocyte, the basophil cytoplasm is often rich in azur granules, coarser and darker than any ever seen in the lymphocyte or monocyte Its presence in the blood is always pathological, it is invariably associated with serious disturbance of the marrow, and all the evidence points to its originating in the marrow Since it is numerous only in myelaemia, Pappenheim assumed that it belonged to the neutrophil series In the leucocytosis of pneumonia a few myelocytes *appear and in a severe case even one or two premyelocytes*, but no leucoblast is seen For this and other reasons he regarded the leucoblast as being more immature than the premyelocyte

In pernicious anaemia however leucoblasts may be present when there are few myelocytes in the blood and no premyelocytes Pappenheim supposed therefore that *in certain pathological conditions this very immature cell* was forced into the blood that (to account for the absence of premyelocytes) onward development then ceased and that it retrogressed into a large mononuclear the so-called leucoblastic monocyte Thus he believed that in the marrow his leucoblast preceded the premyelocyte in the direct line of neutrophil descent but that pathologic life altered the blood to become a monocyte

These facts afford ample evidence of bone marrow origin of the leucoblast but not for its neutrophil descent On the contrary, in the glandular fever of children (*British Medical Journal*, 1927 vol i p 1056) it may enter the circulation owing to the specific action of the toxin on the *monocytosis* This fact and the appearance of the cell in the stained film suggest that it is a monocyte Pappenheim admitted that it was often difficult to distinguish the leucoblast from a monocyte, if it is really such a cell it is always pathological, and the simplest explanation is that it is an immature monocyte (premonocyte) derived from a lymphoid marrow cell (myelomonoblast) This would explain its emergence in malignant disease In internal cancer (liver, lung, kidney) there is usually a considerable *leucocytosis of neutrophilic cells with a few myelocytes*, and monocytosis with a few promonocytes Because the usual stains do not show the cell I abandoned them ten years ago in favour of the following procedure, which I consider the simplest cheapest, and best blood staining method for general purposes

Manson's *methyl ene blue contains 2 per cent of thionine* in a 5 per cent solution of borax in distilled water the water should be boiling when the borax is added but have been removed from the flame This stock solution may be made by any druggist and will keep for some years It is rendered polychrome in small quantities as required by boiling about 10 c cm in a clean test tube gently over a small flame for one minute Fresh solution require this boiling to be repeated three times at intervals of a few hours older solutions are already lightly polychrome and one boiling may be sufficient after which the polychrome fluid is stored by itself in a small bottle preferably pipette topped and will keep good for months A similar bottle contains 1 per cent eosin in solution in distilled water

Into one ounce of distilled water I put four drops of the eosin and two drops of the polychrome solution and mix Films are fixed in methyl alcohol or Jenner's stain for three minutes or longer and are then stained for half an hour to two hours washing briefly in distilled water It is convenient to have two small wide-mouthed bottles with glass stoppers One contains about 15 c cm of fixative and slide are dropped in to be fixed by tilting the bottle sideways It may be used for months all there is no waste The other bottle holds the staining fluid and the fixed films are transferred to it with forceps It is not necessary to cleanse the staining bottle every time but only to renew the staining fluid immediately before each examination

IDIOPATHIC HAEMORRHAGE IN THE NEWBORN

THE value of injecting parental blood in cases of melaena neonatorum seems to be insufficiently recognized and the following clinical details of such a case may therefore be *worth publication*

A multipara gave birth to a girl without instrumental intervention the presentation being a vertex L O A After an easy labour lasting only a few hours the baby was born apparently perfectly healthy The baby became restless thirty hours later and was found to have passed a tarry black stool that was about three ounces in bulk and was covered with patches of bright red blood A diagnosis of melaena neonatorum was accordingly made and 5 c cm of fresh blood removed from a vein in the mother's arm were *injected immediately into the* baby's buttock at 8 a m Subsequent haemorrhages occurred at 12.30 p.m and 5.15 p.m on the same day At 7 p.m *another* 5 c cm of the mother's blood was injected *followed by 1 c cm of* colloidal calcium into the thigh muscles the calcium being repeated daily for a week By the end of the first day the baby was plainly anaemic but only one other bleeding occurred on the day following the first injection—and that was only a very small loss Complete recovery [illegible] apparently in excellent health There was no family history of phlebitis or purpura in the family

We are prompted to publish this case because our textbooks gave any help in the matter having failed when we referred to them after having exhausted treatment except Vol. I. Leaf Melaena Our treatment of the present case was based on reports of a case reported in the *Practitioner Medical Journal* (January 12 h 1929 p 60)

Reviews.

A SYSTEM OF BACTERIOLOGY

THREE volumes of the nine which will eventually constitute the extensive treatise known as *A System of Bacteriology in Relation to Medicine* have already been reviewed in these columns The fourth to appear, volume v,[1] loses nothing in comparison with its predecessors, and will add very materially to the value of this work, which is filling such a long-felt want

This volume opens with a chapter on glanders by F C Minett The subject is perhaps of no very great interest to medical men because of the rarity of this disease in man, but they will read with interest of the satisfactory measures by which their veterinary colleagues have succeeded in controlling, and in some countries exterminating, the disease Up to 1907 about 1,950 horses on an average were annually affected in this country, since 1926 no cases have been reported Following this is a short but most interesting account of melioidosis by W Fletcher, whose name is intimately associated with our knowledge of this glanders-like disease and its causal organism, *B whitmori* The next chapter, by R T Hewlett deals with the important subject of the diphtheria bacillus and diphtheroid organisms The author freely acknowledges his indebtedness to the Medical Research Council's monograph on this subject published in 1923, which Professor Bulloch rightly refers to as the most complete account extant Naturally the information contained in the monograph has had to be condensed for the purpose of this chapter and brought up to date where necessary, the result is a most useful and readable account of the subject The historical note contains no mention of the work of Ramon, which is perhaps a pity, for in the opinion of many, particularly our French colleagues, this constitutes a landmark in the recent history of diphtheria

Chapter iv, which occupies almost half the volume, is devoted to the question of *Bacillus tuberculosis* The many aspects of such an extensive subject as this could hardly receive adequate treatment from a single author, and as many as nine have contributed to this most excellent and valuable account A S Griffith is one of the chief contributors dealing with the morphology and cultivation of the bacillus, experimental tuberculosis, and the spontaneous disease in man and animals We have here the fruits of years of investigation admirably presented The section on allergy and immunity by W H Tytler is good This is a difficult question to deal with There is a wealth of observed facts—some of which are in conflict—which have had various interpretations put on them Tytler has given us a clear and well-balanced account for which those who are unable to keep abreast of the immense literature which has grown up round this subject will be most grateful This chapter contains, in addition, valuable sections on the laboratory diagnosis of tuberculosis by J McIntosh and L E H Whitby, the therapeutic use of tuberculin by A Fleming, the preparation and standardization of this substance by C C Okell, and terminates with an account of chemotherapy in tuberculosis by S L Cummins

Following this are chapters dealing with the other acid-fast organisms, tuberculosis in cold-blooded animals by A S Griffith, Johne's disease by A W Stableforth, leprosy by E Muir, and the non-pathogenic acid-fast bacteria by R St John Brooks Of these the account of leprosy is perhaps the best, and although the section on cultivation loses some of its value, since it was written prior to the recent and apparently successful work of Shiga, it is still of interest as a sound and critical survey of past efforts in this direction The Brucella group is dealt with by J T Duncan, L E H Whitby, and A D McEwen The evidence for the identity of *B melitensis* and *B abortus* is carefully considered, and the danger of diagnosing *B abortus* infection in man by simple agglutination tests is duly stressed Much work remains to be done in this group, and the lines along which investigation is required are pointed out The volume terminates with chapters on *B anthracis* by F W Eurich and R T Hewlett, the non-pathogenic spore-bearing aerobes by R St John Brooks, and two most interesting but short accounts of tularæmia and the bartonellæ by J C C Ledingham and J A W McCluskie respectively

RHEUMATISM

THE treatise by Professor JULIUS BAUER of Vienna on "So-called Rheumatism"[2] cannot fail to be of interest to those who are concerned in the "campaign against rheumatism" in all countries It should be of assistance to the insurance practitioner, and above all to those who are in charge of centres for the investigation and treatment of rheumatic diseases Professor Bauer is himself the principal medical officer of a large sickness insurance fund He realizes the great difficulty of choosing cases for special treatment which follows from the universal want of precise differential diagnosis Modern medicine has done little to remedy the "confusion of tongues," and it will be says, be necessary to "scour out the collecting basin" into which the whole mass is at present poured His own experience in following up large numbers of cases after various forms of treatment has, in the meantime, led him to certain conclusions

What are the true stigmata of rheumatism? Historical descriptive words should not be altogether distrusted The catarrhus articularis of the seventeenth century, and the much earlier conception which regarded rheumatism, like all chills and colds as "simply a flux," have their element of truth, with infection, metabolic disturbance, and over-fatigue as sometimes dominant influences But it is difficult to find, as yet, a common denominator Atmospheric cold and damp, affecting not only the skin and surface layers but the joints, is a ruling etiological factor In sensitive persons it produces various immediate effects, as in neuralgias and myalgias, torticollis, and Bell's paralysis and paroxysmal hæmoglobinuria The secondary reflex and humoral effects of cold are not less remarkable, such as diminution of opsonins, phagocytosis and bacteriolysis, diuresis, albuminuria, œdema urticaria, cardiovascular spasm Strauss has shown that exposure to cold causes an alteration in the skin tissues, with absorption of substances which disturb colloidal equilibrium, and that sensitization so produced may be connected with morbid sensitiveness to cold Of exogenous factors, infection, however, plays the greatest part in causation Infection must be assumed in inflammatory conditions of the synovia, which characterize the most serious forms of rheumatic disease, like rheumatic fever, as well as in primary chronic polyarthritis, although a constitutional and possibly allergic factor may be present in these diseases On the other hand, the very common degenerative conditions are not infective, although often followed by secondary reactive inflammations There is no proof that endogenous—for example, metabolic—errors can of themselves cause an inflammatory arthritis, although the author admits that "an endogenous factor proper to the organism seems to be a necessary factor in the disease" Anomalies of metabolism may be either conditional and paratypic, or present *ab ovo* and genotypic It is clear that in the causation of the rheumatic diseases they operate in connexion with exogenous factors He considers that the endocrine factor is much overrated, although answerable for many of the polyalgias as in mechanical irritation of the peripheral nerve-endings in obesity

With regard to treatment the discriminating use of protein therapy is commended Baths appear to act as counter-irritants, affording in effect another form of reiztherapie, but their action has never been fully explained—thermal, mechanical, on the skin and nervous tissues, by absorption, and psychic It is worthy of remark that at the present time the oldest of remedies,

[2] *Der sogenannte Rheumatismus* Von Dr Julius Bauer *Medizinische Praxis* Band vii Dresden und Leipzig T Steinkopff 1929 (6 × 8½, pp vi + 142 16 figures, 6 plates RM 9)

which are physical and also the commonest of diseases, the rheumatic are both urgently in need of investigation not so much by laboratory experiment—which is indeed difficult or impossible—as by accurate observation of individuals undergoing treatment. Not a few students of the rheumatisms prevalent in northern countries have that double objective in view. To attain success specialists in all forms of treatment are needed. Freund's opinion is quoted, that many cases of primary chronic polyarthritis are intolerant of heat, and examples are given showing the difficulty of advising patients in the use of baths, and of "sheltering them from bad effects." A practical rule of no little importance is noted: that the functional possibilities of joints must be carefully conserved, by movement given at times of freedom from pain. For this purpose baths and local applications of heat, by hot air or mud or diathermy, may be of much assistance.

THE IMPORTANCE OF A BIOLOGICAL SOCIOLOGY

IT is not hard to identify "A SURGEON" who reveals his initials as C. J. B., writes from Leicester and gives the titles and occasions of his thirteen *Essays and Addresses*[1] written between 1911 and 1929. Throughout them runs the *motif* of an earnest desire to improve the moral, social, and physical state of the race. The method of presentation is thoughtful, free from emotional appeal and based on the application of biological principles. As shown in his Francis Galton Memorial Lecture given in 1928 before the Eugenics Society on "Some causes of racial decay," it is important to bring home to the minds of statesmen and indeed of everyone, the realization that present sociological methods are not yet based on sound biological foundations. Another urgent need is for a national census of quality as well as of quantity, so as to render possible reliable comparisons of physical and mental qualities now and at some future date. The proper attitude of the State and of society in general to diseases and disabilities which are due to unphysiological living and anti-social conduct, such as alcoholism and venereal disease is discussed, and the author insists on the need for educating the public so as to create a "national health conscience" which recognizes that it is wrong to be ill if disease is avoidable. The latest of the addresses in this volume, where every article is interesting, is that on the prevention of mental deficiency given last November and here again education of the public is clearly desirable to obtain united and widespread efforts for improvement.

GRAY'S "ANATOMY"

THE twenty-fourth edition of Gray's *Anatomy*[2] would be noteworthy if for no other reason than that it has appeared under a new editor. Professor T. B. JOHNSTON, in succession to Professor R. Howden, who has been responsible partly or entirely, for no fewer than nine editions issued during the last twenty-five years. Although a textbook of such maturity and popularity tends naturally to become stereotyped, the progress of the subject cannot fail to offer opportunities for effecting improvements either by adding to or amending the work, and such opportunities the new editor has seized nowhere better than in the section on embryology. This section he has thoroughly revised in the light of recent research, having amplified it by twenty-nine pages of text, added thirteen new figures and so modified several figures that have been retained as to make them less diagrammatic and more realistic. In other sections we are glad to note that he has made no attempt to sacrifice unduly the semi-diagrammatic and topographical figures the presence of which has always been one of the most helpful features of the work. Professor Johnston's chief and most successful contribution seems to us to be in the effort he has made to elucidate the structure of those regions of the body which present special difficulty to the student. We would cite as examples such figures as those showing the structure of the wall of the buccopharynx as seen from within, the relations of the posterior belly of the digastric muscle, and the interior of the left side of the peritoneum. Less successful is Figure 695 illustrating the relations of the subclavian artery at the root of the neck, though the failure is due in some measure to the inverted position the figure occupies on the page.

Despite its many excellencies the work is not entirely above criticism. We suggest, for example, that the description of the fibular attachment of the calcaneo-fibular ligament should be made to conform with the very accurate representation in Figures 539 and 543, that the tendon of the extensor carpi radialis brevis should be credited with an attachment to the base of both the second and third metacarpal bones, and that attention might be drawn to the groove—only a little if at all less distinct than that produced by the tendon of the peroneus longus on the under-surface of the cuboid—which the tendon of the tibialis posticus makes on the under-surface of the scaphoid. We feel no little reluctance in drawing attention to what are after all small matters, nor should we have done so but for the fact that Gray's *Anatomy* is by way of being a national institution. It is a great pleasure to feel that in the hands of Professor Johnston the work will continue to keep the proud position it has held for the better part of a century—the most popular textbook on anatomy in the language.

CONGENITAL TALIPES

CONGENITAL club-foot has had many essays and books devoted to its elucidation in the past hundred years, but the last word has yet to be said. The work of Mr. E. P. BROCKMAN[3] which earned the Robert Jones gold medal of the British Orthopaedic Association for 1928 should go far to settle some moot questions. Mr. Brockman in 110 pages, sums up adequately the history of the subject, describes and discusses the normal anatomy of the leg and foot and the pathological anatomy of club-foot. As to the vexed question of the etiology of ordinary congenital club-foot he summarizes his remarks thus:

> Congenital club-foot is caused by a primary failure in development to their full state of all the tissues of the foot. This involves the bones, the ligaments and the muscles. We know nothing of the influence that controls the development of the fertilized ovum nor do we know why it should sometimes fail either partially or completely."

To this we would add that all those who have had much experience of the treatment of congenital talipes equino-varus must agree that this developmental defect comes out clearly in the tendency of an apparently cured club-foot to relapse as growth goes on, a tendency which seems to be caused by an inherent vice of development which is continually reasserting the deformed type. The explanation of this "relapse" offered by Mr. Brockman and others—namely that it is really due to a primary failure to alter the positions of the bones of the hind foot—seems to us rather to beg the question by its assumption that such failure has escaped the notice of surgeons thoroughly familiar with deformity and normality. With this and some minor exceptions we agree with Mr. Brockman's conclusions.

[2] *Anatomy Descriptive and Applied*. By Henry Gray, F.R.S. Twenty-fourth edition. Edited by T. B. Johnston, M.B., F.R.C.S. London and New York: Longman, Green and Co. 1930. (Roy. 8vo, pp. xvi + 1466; 1391 figures. 42s. net.)

medical man a new relation to the social order In a graphic passage, Dr Fishbein notes the change that is coming over mankind "the big boned, muscular, prognathic, hairy, stupid ape man has given way to the smooth skinned, bald, slightly corpulent, spindle legged, and thin armed mental dynamo For the sharp nosed, keen eared savage with quick vision, sensitive touch, and rapid response substitute the alert brained, heavily be spectacled, false toothed director behind a desk" Perhaps the position of modern preventive medicine cannot be expressed better than by the admirable dictum that "our hygiene is changing from a moral to a scientific hygiene" Throughout the volume runs the strong current of common sense that should counteract the fads, fancies and quackery which mankind delights in and against which Dr Fishbein has elsewhere waged a vigorous war

We have now received the fourth volume of a series of publications on medical radiology,[7] compiled by various German writers, notices of the three previous ones appeared on December 25th, 1926 (p 1231), and August 25th, 1928 (p 345) The present volume deals particularly with the application of radiology to internal diseases, and the subjects considered include its employment in detecting variations in the position and form of the stomach, examination of the upper urinary passages as a means of diagnosing abdominal tumours, the relation of ultra-violet light and vitamin D to rickets, the causation of pigmentation and the part it plays in protecting the body against the evil effects of certain irritating rays, light erythema, the histology of uterine carcinoma in its relation to radiotherapy, the biological principles concerned in the treatment of cancer, radiology in connexion with operations on the stomach, and diathermy in the treatment of disorders of the throat, nose, and ear This volume, like its predecessors, is freely illustrated, the indexes are good, and the bibliography is extensive

Miss GULLAN'S well known *Theory and Practice of Nursing*[8] has reached its third edition, and has been brought up to date It is a pity that the new preface should contain two misprints, one in particular referring to the appendixes being most unfortunate The appendix in question (No 3, and not No 4) deals with "Food tests and digests," whatever that may mean and should either be omitted altogether or included as an integral part of the chapter on digestion Apart from this comparatively small point the book can be warmly commended to all nurses for its sound teaching, and the chapter on private nursing should be thoroughly mastered

Presumably there is a lay public which likes its flesh made to creep, and for that public Dr NICHOLAS KOPELOFF, research associate in bacteriology in New York, has produced an imposing volume, *Man vs Microbes*[9] He describes it as a "comprehensive volume on microbes for the intelligent layman, an aspect of the human adventure too long neglected" He does not neglect to describe the beneficent germs which have been harnessed by man to agriculture and industry The book is written in a lively manner, and includes accounts of all the more important micro-organisms and of the diseases they produce But it is perhaps doubtful whether it is necessary to quote Chapin's diatribe *against saliva in connexion with the* disease diphtheria. What is the poor layman to do when he learns that 'the cook spreads his saliva on the muffins and rolls, the waitress infects the glasses and spoons, the reader moistens the pages of his book, everyone is busily engaged in the distribution of saliva"? Dr Kopeloff does not emphasize sufficiently the curious fact that we do not all contract diphtheria

Medical men have long desired more authoritative information on the frankly cosmetic side of dermatology, and they owe a debt of gratitude to Messrs REDGROVE and FOAN, who, having previously dealt with hair dyes and perfumes, now give us a volume revealing the secrets of *Paint, Powder, and Patches*[10] There is not quite so much information of medical interest in this as in their former book entitled *Blonde or Brunette?*, as they have approached the subject more from the theatrical and cinema side, but there is much that will be useful for dermatologists to know about face powders, creams, and lipsticks, and the wonderful transformations possible by means of effective "make up" have a fascination for many besides professional mimes

ST DUNSTAN'S MASSEURS

ADDRESS BY SIR THOMAS HORDER ON PHYSIOTHERAPY

The blinded soldier-masseurs of St Dunstan's held their annual luncheon and reunion at the Langham Hotel on July 25th, when they were addressed by Sir THOMAS HORDER, Bt The Prince of Wales sent a message saying that he was very pleased to hear of the great success which had been attained by more than one hundred blinded soldiers who had been trained in the practice of massage and electrotherapy

Captain IAN FRASER, chairman of the executive council of St Dunstan's, who presided, said how much St Dunstan's and the blinded soldiers under its care were indebted to the medical profession as a whole Whenever and wherever St Dunstan's had called upon consultants, specialists, or general practitioners, these had given their assistance, either voluntarily or at very much reduced fees, and this represented a really generous contribution towards St Dunstan's work Special kindness and consideration had been shown also by hospitals, particularly their out patient departments Although there was actuarial assurance that the lives of blinded soldiers as a whole were likely to be of normal duration, it was nevertheless a fact that a considerable proportion of them suffered a good deal from the direct and indirect effects of their wounds He mentioned that figures prepared by Sir Arnold Lawson and Mr A W Ormond who between them had seen over 1,800 St Dunstan's cases showed that in 41 per cent the blindness was due to wounds caused by high explosives, in 29 per cent to bullet wounds, and in 3 per cent to other traumatic causes, while in the remaining 27 per cent it was due to non traumatic causes such as detachment of the retina, cataract, optic atrophy, and aggravation of latent conditions as a result of hardship Not more than one or two men, to his knowledge, had their sight materially affected by gas

Sir THOMAS HORDER said that he spoke as one who was peculiarly interested in physiotherapy, meaning by that term the various methods of treating patients which began by means of the human hand The men to whom he was speaking had a special adaptability for this method of treatment The deprivation of one faculty made the others more acute, while those who had as it was termed, "all their faculties" tended to drift into using them inefficiently The blind were obviously auditives, but those he was addressing were making themselves into very skilled tactualists One thing which he urged them to do was to state quite clearly, and in every legitimate way, that they were certified The public should know that they had a definite and recognized foundation for what they professed

Although physiotherapy was a very progressive form of therapeutics, Sir Thomas Horder said, he himself was rather conservative in his choice of methods He preferred methods well tried and understood to those new ones which made an appeal to the mysterious in the mind of the patient He also preferred simple methods to complex, he had a great faith in the possibilities of the human hand, and distrusted machinery Some patients had a pathetic belief that a machine could not lie, they wanted, for example, not the physician's assessment of their degree of cardiac insufficiency, but an electrocardiogram, forgetting, of course, that whatever was ascertained, whether by the machine or by the senses, had to be interpreted by the experienced judgement He believed that an immense opportunity for advance in physiotherapy lay in the direction of massage and manipulation Masseurs were tempted sometimes to substitute for physiological and voluntary movements and functions "passive movements," as they were termed They attempted to do for the patient's locomotor apparatus what sometimes members of the medical profession attempted to do for the patient in general—namely, to lead his life for him It was imperative in trying to restore the functions which were in abeyance not to introduce substitutes for what the patient should do for himself There were cases in which the whole movement must be entirely passive to begin with—in certain affections of the heart, for example—but it was most important to recognize the stage when the patient might begin to participate voluntarily in the movement himself No amount of massage or electrical stimulation had the same physiological value as the natural movements carried out by the patient under guidance and supervision

Sir Thomas Horder also reminded his audience that their work, like that of the medical practitioner was based on science The temptation to humbug a patient—and there were patients who liked to be humbugged —must be resisted Massage was *too valuable too integral a part of physiotherapy* to be placed in the background while one talked to the patient of bones out of place of which there was no evidence and so forth Many of them could double their income if they were prepared to substitute for good honest scientific work a certain amount of humbug Finally he spoke of the moral effect of the masseur's work The encouraging manner of the masseur was of value quite apart from what he did with his hands Not seldom the masseur knew more about the patient than the doctor did, but he should not neglect the doctor's point of view Lack of co-operation with his medical supervisor meant failure If the masseur discovered anything which the doctor had not appreciated he should not tell the patient, but should tell the doctor, who would value any information given in the right spirit Many masseurs aimed at too rapid results They forgot that all physical methods were educational in nature. Just as a kind of mental dyspepsia could be produced by forcing the mind too quickly, so irritation and fatigue resulted from an over keen physiotherapy He himself was often content to find at the end of a week a result which *the masseur had been disappointed not to have got within* twenty four hours Often a masseur's work might be spoilt by disregard of the patient's psychology One of the most frequent complaints was the perpetual talk in which many masseurs indulged while giving the treatment He himself often employed blind masseurs, but if he had a chance of employing dumb ones he would be tempted to give all his work to them

CORRELATION BETWEEN INTELLIGENCE TESTS AND WRITTEN AND PRACTICAL EXAMINATIONS

BY

R C GARRY, M B

(From the Institute of Physiology The University Glasgow)

Access to marks gained by second-year medical students, both in academic examinations during the ordinary course of their work in physiology and in a series of intelligence tests, gave an opportunity of finding out how far skill in the one was correlated with skill in the other

The usual examination paper in physiology calls for simple reproduction of facts which have been presented to the candidates at some previous date To gain a good mark in such an examination *it is only necessary to possess a retentive memory* and a fair degree of steady application to the assimilation of facts Intelligence tests are more or less empirical productions, yet they usually differ from the common form of examination in demanding something more than reproduction of acquired information It is common knowledge that the type of student who excels in written examinations may fail lamentably when confronted with practical work, and that the results of intelligence tests are often at variance with the results gained by the *usual methods of examination* Practical work, though of necessity greatly influenced by what is taught, makes a definite demand on qualities which can be acquired neither from books nor from teaching nor even from actual practice, and these qualities may approximate to those tested in the course of an intelligence examination

The ordinary course in physiology in Glasgow demands both attendance at lectures and the performance of practical work For convenience the academic year is divided into three terms, each of ten weeks' duration, and at the end of each term there are two class examinations —one by a written paper, the other by a practical test The sequence of lectures is uninfluenced by the terms and the three written examinations are of exactly the same type Each consists of a paper with three questions to be answered within one hour, and asking for a simple restatement of current physiological teaching The practical work, however, deals with three separate aspects of physiology, the first ten weeks being devoted to experimental physiology, the second to chemical physiology the last to histological physiology The three practical tests, therefore are alike in demanding something in addition to the power of reproducing acquired information

The marks used in the present investigation were all obtained from the same students sitting the same examinations The intelligence test—"Group Tests Series 33" of the National Institute of Industrial Psychology—was given at the outset of the year's work Attendance was compulsory, no warning was given, and over 140 students sat the paper The 140 papers were ultimately whittled down to 103, a certain number of the students had sat the same intelligence paper in the previous year a few several years before, and their papers were ignored The papers of students whose native language was not English and those from students older than the average student were also omitted The previous academic instruction of the students was the same in every case, and the ages varied from 18 to 20 years The intelligence tests were left uncorrected until the students concerned had passed through the entire year's course in physiology Thus those who corrected the class work had no idea of the intelligence test mark gained by individual students

Correspondence between any two series of marks was estimated by finding the coefficient of correlation The results are given in the accompanying table

Intelligence Test Series with	Written Paper		Practical Test	
	Correlation Coefficient.	Probable Error	Correlation Coefficient	Probable Error
Average of all the marks ...	+ 0.19	0 063	− 0 36	0 057
Marks in experimental term	+ 0.23	0 060	+ 0.23	0 060
Marks in chemical term ...	+ 0.003	0 065	+ 0.47	0.050
Marks in histological term ...	+ 0 17	0 063	+ 0.24	0.062

Correlation between intelligence test results and the results of practical work is low, but in every case *significant This cannot be said of the correlation between* this intelligence test and the written papers The correlation coefficient between the average mark gained in the three written papers and the average mark gained in the three practical tests is −0 44, with a probable error of 0 053

Owing to the distractions of student life, it is possible that the results of written papers may not represent the true ability of a large number of undergraduates An intelligence test for which no preparation is required presumably indicates the total ability of each candidate In the degree examination, however, it should be otherwise, because the great majority of those who present themselves have worked reasonably well and feel fairly confident

The correlation coefficient between the results of the same intelligence test and the marks gained by the same group of students in the degree examination at the close of the year's work was only + 0 13, with a probable error of 0 057 Thus it seems that the striking want of correspondence between intelligence test results and the results of written class examinations cannot be attributed wholly to outside distractions operating inimically on the class work with a special bias against the written papers Incidentally, those students who had sat the same intelligence test the previous year showed *without exception* a definite increase in marks *in comparison* with their previous attempt

Summary

The results of written examinations of practical examinations and of an intelligence test obtained from a uniform group of medical students showed that the results of the intelligence test gave consistently a significant though low correlation with the result of the practical work, but with the results of the written papers the correlation was lower and not consistent

It is suggested that the qualities of value in dealing with an intelligence test approximate more closely to those which are useful for dealing with a practical examination than to those which are useful in answering a written paper

I am deeply indebted to Professor Cathcart for advice and for assistance.

British Medical Journal.

SATURDAY, AUGUST 9TH, 1930

A NATIONAL MATERNITY SERVICE

The publication this week of the interim report of the Departmental Committee on Maternal Mortality and Morbidity (of which a summary, with some comment, will be found on page 223) should mark a further stage of progress towards the establishment of a national maternity service. The first detailed proposals in this direction were those of the British Medical Association approved by the Representative Body at Manchester in July last year. They were shortly followed by similar proposals made by the Departmental Committee on the Training and Employment of Midwives, and by other bodies or associations. There was an influential demand, and in some quarters an expectation, that the new Government should introduce legislation to the end indicated, even in its first Parliamentary session. This demand, or expectation, has not been fulfilled. There were no doubt several reasons for postponement, but one of those officially given was the desirability of waiting for the report of the Departmental Committee on Maternal Mortality and Morbidity. A more insistent desire will now be felt for Government action at an early date on one of the most urgent problems of the time, it is to be hoped that the fact that the report of that committee is interim and not final will not be made a renewed excuse for delay. On the particular issues relative to the suggested legislation there is now full information available, though there is need for further consultations with regard to some practical medical and administrative problems, and important financial considerations have to be taken into account. So far as the British Medical Association, representing the organized profession, is concerned with these, action need not be unduly delayed.

The proposals of the Association towards the establishment of a national maternity service have, during the past year, had a wide publicity and received a large measure of approval. They are published as a separate document, slightly amended from the form in which they were printed in the Annual Report of Council in 1929 (*Supplement*, June 29th, 1929, p. 258). An explanation of two points on which there had been some misunderstanding will be found in the Annual Report of Council this year (*Supplement*, April 19th, 1930, p. 134, para. 90), and this should be noted. The report of the Departmental Committee on Maternal Mortality is a valuable reinforcement of the Association's scheme in four respects. Emphasis is laid by the committee on the urgent need for such a scheme. "They wish to state explicitly their view that at present the maternity services are not yielding their potential value, and are not proving a solution of the problem of maternal mortality because of the lack of co-ordinated effort." The report lays down exactly those essential conditions and indicates exactly those essential services which the Association's scheme is devised to provide. In regard to the main differences between the proposals of the Association and the suggestions of the Departmental Committee on Midwives which reported last year, the present committee's report inclines decidedly to the former. These differences are noted in this year's Annual Report of Council (*Supplement*, April 19th, 1930, p. 133, para. 86): they relate to the provision of a doctor's services in a normal case, to the admission to an institution at the patient's option, and to the inclusion in an insurance scheme of the pauper class. Again, the Association's proposal that in certain circumstances a portion of the cash maternity benefit should be payable in advance (which was not noticed by the earlier departmental committee) is supported in the present report. Further, it is gratifying that support is given by the committee to an additional point in the Association's policy in a statement worded as follows: "It is essential that there should be cordial co-operation on the part of the medical profession and of practising midwives, and that for this purpose some kind of co-opted representation of practitioners and of midwives on the committees or sub-committees concerned should be provided for."

Two other matters definitely relevant to a national maternity service are dealt with or referred to in other sections of the departmental committee's interim report. The more important of these relates to the use of anaesthetics and analgesics in obstetric practice. It may be remembered that the Departmental Committee on Midwives said that "it would be to the public interest if some professional body would issue at an early date some pronouncement as to the advisability and place in labour of anaesthetics and sedative drugs generally." In response to this the Council of the Association set up a special committee to report on this matter, and this report was submitted to the departmental committee. There were similar reports from the Royal College of Physicians and from the British College of Obstetricians and Gynaecologists. Meanwhile a well-intentioned but misguided effort had been publicly made to provide anaesthesia for every maternity case. All the reports referred to point out the undesirability of these drugs in certain classes of cases and the danger, either to mother or to child, of their use by persons other than properly qualified medical practitioners. The committee's report fully endorses the position held for so long by the British Medical Association, nevertheless, the provision for anaesthesia is an essential part of any national maternity service.

The other subject referred to is the scale of fees to be paid to practitioners called to a case by midwives. This is important not merely as part of, but prior to, a national maternity service. The earlier departmental committee came to the conclusion that the present scale should be reconsidered by the Minister of Health in consultation with the British Medical Association, and the present committee's report states that it does "not feel that the present scale of fees paid by local authorities under the Midwives Act could be adopted without revision." These expressions of opinion amply justify some such revision as is now asked for by the Association, after careful consideration by the Council and full debate at the recent meeting of the Representative Body.

THE ORIGIN OF CUSTOMS AND BELIEFS

An experienced medical practitioner who had watched the fate of most of the leading men of a great industrial centre for more than a generation once said that a man who had lived a strenuous life in business commonly died within a couple of years after retiring if he had failed to provide himself with a hobby. Men of active mind who have reached a vigorous old age have almost invariably had some second subject to which they could turn, for such men the best relief is to change the current of thought. Granted the wisdom of having some subject of interest outside the

daily round it may be wise to choose one in which it is fairly easy to attain moderate excellence as an amateur No one is better placed to find a congenial indoor hobby than a medical man, for his early training gives him the elements of such sciences as botany and physics and chemistry, while the history of medicine opens innumerable by-paths along which he may wander If it be generally true of all men that the proper study of mankind is man it is in a very particular sense true of the members of our profession Every day in the ordinary practice of medicine are encountered customs habits prejudices, even superstitions, rooted in the dim barbarous past, but influencing the actions of civilized men and women to-day—*the survivals of pre Christian religions and of prehistoric folk medicine* Therefore of all hobbies perhaps the most appropriate for us is to browse in the literature of the beginnings of man and whenever opportunity serves to correct our impressions by seeing and handling his handiwork

It may savour of flippancy to suggest as a suitable subject for a hobby any department of a science calling for so much industry, erudition and critical acumen as is required from one who would make serious contributions to anthropology or ethnology The impression produced by a first attempt to gain some acquaintance with the literature of that part of anthropology concerned with the history of the beliefs, customs and practices of mankind is one of bewilderment Its mass is already enormous, its contents confused and contradictory, and the interpretations conflicting Before going very far, however a remarkable similarity is perceived in these respects between races widely separated in time and space Upon this all authorities are agreed, but when an explanation is sought great divergence of opinion is disclosed The problem as stated some ten years ago by Sir James Frazer is How are we to explain the numerous and striking similarities which obtain between the beliefs and customs of races inhabiting distant parts of the world? Are such resemblances due to the transmission of *the customs and beliefs from one race to* another, either by immediate contact or through the medium of intervening peoples? Or have they arisen independently in many different races through the similar working of the human mind under similar circumstances? *There are difficulties in the way* of either explanation and to Sir James Frazer they appeared so strong that he held both causes to have operated, believing that many of the resemblances are to be explained by simple transmission with more or less of modification, *from people to people*, and many are to be explained as having originated independently through the similar action of the human mind in response to similar environment That there has been local modification and transmission of the belief or custom so modified nobody doubts, and Frazer's compromise does not seem to help very much It is, in fact, less a compromise than a restatement with very slight modification of the original hypothesis of diversity of origin

On the other hand, Professor G Elliot Smith, one of the most vigorous and best equipped of the most modern school, after remarking that the clear light recent research has shed upon the earliest literature in the world has done much to destroy the foundations upon which the theories propounded by scholars have been built up, has asserted that the prevailing doctrine of the independent development of human beliefs and practices ' is not a safe basis for the construction of theories . At best it is an unproven and reckless speculation I am convinced it is utterly false Without presuming to take sides, the amateur *ethnologist will* pay due heed to this very definite opinion on a matter of perennial interest to students of mankind

THE PARLIAMENTARY SESSION

In the parliamentary session which began on June 25th *1929, and ended on August 1st 1929*, the legislative output has not been commensurate with the time expended some important measures promised in the King's Speech have been dropped after introduction, or not introduced at all The promised bill to codify and modernize the Factory Acts is in the latter class But apart from that measure bills of direct medical interest had the good fortune which of late years the Ministry of Health seems to command for most of its proposals Measures which are now on the Statute Book include the Mental Treatment Act, the Highlands and Islands (Medical Service) Additional Grant Act the Workmen's Compensation (Silicosis and Asbestosis) Act, the Housing Act, and the Housing (Scotland) Act The Education (Scotland) Act, which was introduced by Dr Elliot, will facilitate the provision of milk to Scottish school children The Road Traffic Act as passed includes a section providing that voluntary hospitals if they treat those injured in road accidents shall receive a share of the sums paid on third party insurances This provision was inserted by unofficial members in the House of Lords, and supported by others in the House of Commons so firmly that the Government though doubting its practicability could not insist on its deletion *Bills of medical interest* which failed to pass had all been introduced by private members Among them were the Poor Law Officers' Superannuation Bill (Dr Vernon Davies), the Midwifery and Maternity Bill (Mr Alpass) the Protection of Animals Bill and the Protection of Dogs Bill For once the debate on the Ministry of Health Estimates was dominated by a health subject—the report of the Government actuary on the increase in sickness benefit under the National Health Insurance Act Mr Greenwood announced that this matter *would be further investigated* He also made the first *public announcement of the Government's contribution* toward the establishment of a centre in London for postgraduate medical work, to be available for panel practitioners as well as for medical men from the Empire overseas *Maternal mortality was chosen as the subject for* another full day's debate in the House of Commons, and on this the discussion was keen Interpellations or briefer debates have been concerned with the shortage of medical officers in the Navy and Army, the retired pay of P.A.M.C officers, *colonial medical services, the recognition of Indian* medical degrees, tuberculosis in cattle, diet and the teeth and psittacosis, a subject in which the House took still more interest Bills promoted by local authorities included one from Cardiff which proposed special arrangements for the early notification of cancer, *and another which proposed* that Hull should acquire and control a special stock of radium for the use of *local medical men* The latter provision was modified during the passage of the *bill* During the long debates on the Mental Treatment Bill some Labour M.P.s exhibited a prejudice against the Board of Control and a desire to keep the early treatment of mental cases away from recognized mental hospitals and out of the control of the Board Apart from this and from an echo of the *dictum* of Mr Morrison Minister of Transport against the voluntary hospital system no suspicion of antimedical prejudice has marred the session The Parliamentary Medical Committee stronger in numbers than ever before has worked well together Its last business during the session was to ask the Minister of Health to consider the

establishment of a central advisory council to correlate the work of rheumatism clinics A Public Health Advisory Committee of the Labour Party has also emerged as a separate entity Meetings were held at the House of Commons during the session by M P 's and others who desired to bring about the establishment of a national medical service, but their campaign was suspended until its leaders had considered the new scheme propounded by the British Medical Association Mr Greenwood, as Minister of Health, has been fully aware of the importance of the health side of his department Among medical M P 's Dr Vernon Davies, Dr Fremantle, and Dr Morris-Jones have contributed most to debates Dr Salter and Mr Somerville Hastings have organized the work of the Parliamentary Medical Committee, and the former was active on the Road Traffic Bill Little was heard during the session from the anti-vaccinationists, and the anti-vivisectionists chiefly confined themselves to questions about the Porton experimental station for investigating poison gas A petition in favour of the recognition of osteopaths was presented in the closing days of the session

PURULENT TUBERCULOUS PLEURISY

According to the classical teaching surgical intervention is undesirable in the treatment of purulent tuberculous pleurisy, *the treatment of election being by medical means*, with the addition of careful needling As chest surgery advances this view is changing, and it is important that the precise indications for operative measures should be properly understood In a recent monograph[1] Drs F Dumarest, P Rougy, and M Guillemmet discuss very clearly how team work can be applied to the treatment of this complication of phthisis Dr Dumarest and his collaborators hold that much of the confusion that exists in this subject is due to the fact that all varieties of purulent tuberculous pleurisy are improperly lumped together They accordingly classify cases in definite groups, and for the clinical types in each group they lay down principles of treatment The first condition they consider is "cold abscess of the pleura" with or without a coexisting pneumothorax Here the general condition of the patient is remarkably good, and the complication may be discovered almost accidentally, complete reabsorption of the pus is possible, and, provided no distress is being produced by the effusion, *strictly medical and hygienic measures should be employed* Needling of the chest may be necessary when severe dyspnœa is present, but there is always the risk of producing a permanent fistula In cases of pneumothorax complicated by a cold abscess which does not absorb and which recurs after tapping, the authors recommend the production of oleothorax Another type of purulent tuberculous pleurisy is that in which a simple pleural effusion appears to have become infected Although in a patient with such a pleurisy the clinical condition is much worse than in the cold abscess type, and is marked by fever and signs of systemic disease, direct evidence of secondary infection is not obtained easily Such cases in their early stages may be difficult to diagnose from simple pleurisy with effusion, and at the beginning of treatment removal of fluid with gas replacement is advised As soon, however, as the general condition of the patient makes it certain that the effusion has become infected, *lavage of the pleura should* be undertaken by means of certain antiseptics, notably weak iodine solution, introduced through a special three-way cannula If this treatment fails to ameliorate the patient's condition then the question of incision of the pleura and drainage has to be considered, but this operation should be performed only as a last resource In the third group of cases the pleural effusion is frankly septic with bacteriological evidence of a mixed infection Here the exact state of the pyothorax must be carefully considered, whether it communicates with a bronchus or not, and whether the visceral layer of the pleura is intact or destroyed over a wide area of lung In closed pyothorax cases, tapping of the effusion with pleural lavage may be tried first, but opening of the pleura and drainage is usually necessary The aim of treatment is to secure adhesions between both layers of the pleura and obliteration of the affected area This is a rare occurrence after simple drainage, and some form of thoracoplasty, with or without phrenic nerve section, is frequently necessary In cases where there is a fistula between lung parenchyma or bronchus and the infected pleural space, the treatment is different because constant reinfection of the pleura is bound to occur If there is *a small infected cavity* in the pleura, with a sound lung on the opposite side, thoracoplasty should be considered as an immediate proceeding, but if the whole of one side of the chest is filled with pus and *the pyothorax is "open" then every effort must be made* to reduce the amount of fluid by tapping, pleurotomy, and phrenicotomy so that thoracoplasty can be performed later While Dr Dumarest and his colleagues are fully agreed that a tuberculous effusion is best left alone as long as possible, they have set out very clearly in the monograph here summarized the exact indications for further treatment when active measures become necessary

THE SCIENTIFIC BASIS OF MASSAGE

UNDER one name or another massage has been used for ages, and in many countries as a means of treatment of many morbid conditions, and for more than a generation surgeons have taken its claims seriously and have prescribed its application, but without much exact scientific knowledge *of its modo of action* Attempts have been made to fill the gap in our knowledge, of which a serious one is represented by an inquiry made by Drs Pemberton, Coulter, and Mock, the report of which has been approved by the Council on Physical Therapy of the American Medical Association, and its first part published in the journal of the association[1] From the evidence brought forward, and from former essays on the subject, it seems safe to conclude that massage increases local metabolism and the excretion of waste products, stimulates the circulation, and also reacts on the nervous system as manifested by the reflexes Unlike volitional muscular contraction, it does not increase the formation and excretion of lactic acid In persons who are unable to take active exercise it may compensate for the want of the effect of muscular contractions on the return of venous blood to the heart The authors of this paper describe the three varieties of manipulations with their subdivisions, dear to the physiotherapeutist, but not held to have so great an importance by many surgeons The Council on Physical Therapy of the American Medical Association condemns the use of mechanical exercises such as those introduced by Zander as long ago as 1857 on the following grounds

1 Volitional effort is not encouraged
2 The same results could be accomplished without an apparatus
3 Treating only one part does not give any of the advantages of general exercise
4 The use of such apparatus is monotonous, and the patient loses interest in treatment
5 The effect is that of massage and lacks the physiologic benefits of exercise
6 Such apparatus is definitely dangerous

No instances of these evil effects are, however, adduced Most surgeons will approve of the judicious use of massage in the treatment of sprains, including those forms of sprain which really form the traumata of dislocations Except in the case of children we think that most will accept the approval of Lucas-Championniere's teaching as to the use of massage for fractures, although few nowadays will go far with him as to the advisability of discarding splints In

[1] *Traitement des Pleurésies Purulentes Tuberculeuses* Par F Dumarest, M Guillemmet, P Rougy La Pratique Medicale Illustree Paris G Doin et Cie 1930 (7¼ × 10 pp 42 4 plates 16 fr)

[1] *Journ Amer Med Assoc*, June 21st 1930, p 1989

sprains and fractures it would appear that the role of massage is the restoration of the circulation which has been impaired by rupture of capillaries An elaborate tabular list of suggestions for starting physical therapy in fractures is appended to this paper, in which the method of immobilization, the position, the duration of splinting, the use (if any) of a convalescent brace and the date and duration of physical therapy are stated for every typical injury There are also paragraphs on the applicability of massage to the treatment of stiff joints and amputation stumps, and the paralysis of anterior poliomyelitis and Little's disease A note of caution is struck in the discussion of these last two conditions, of which we strongly approve If there is little or nothing that is new in this report it at least reminds of ascertained facts which should be remembered It is to be continued in a later issue of the *Journal of the American Medical Association*

THE ANTI SCURVY VITAMIN IN APPLES

THE investigation of the vitamin content of various foodstuffs is one of the less spectacular but highly important phases of the medical research which is at present making steady and regular progress 'Routine" research sometimes receives rather disparaging comment, it is apt to be forgotten that every big advance leaves, almost in proportion to its magnitude, a large number of points of detail which must be worked out if full advantage is to be taken of the ground gained Thus "following up" is often tedious, and is usually expensive in both time and money, yet it is absolutely essential to the progress both of practice and of theory, and not seldom does it lead to unexpected and new advances The report[1] by Bracewell, Hoyle, and Zilva, on the anti scurvy vitamin in apples, issued by the Medical Research Council is an example of a careful and systematic "follow up" of the vitamin story The work, as the authors make clear, *is part of a much wider scheme*, which aims, partly at least at gaining fresh knowledge of the nature and properties of the vitamin itself Several facts of practical importance emerge It seems to be finally shown that some apples are a reasonably good source of the vitamin Cold storage has only a slight deleterious effect—an important point, in view of the extent to which imported apples are eaten *Roasting the apples in their skins* destroys the vitamin only to a negligible extent A more interesting matter from the scientific point of view is the very queer distribution of the substance It is well known that lemons are rich in vitamin C, and that limes are poor, and that the substitution of limes for lemons in the British Navy had disastrous results It is more startling, however, to realize that there are tremendous differences in the vitamin C content of different types of apples, one kind in particular, Bramley's Seedling (a cooking variety), being far richer than any of the other kinds tested This difference seems to be truly dependent upon the species of apple, and not upon the age of the tree, the soil upon which it is grown or the time of year (provided the apples are suitable for picking) at which the fruit is gathered To those who are not horticultural experts one apple tree looks very like another, and such marked differences are unexpected, although in some Continental work, not yet published, equally striking differences between closely allied fruits are demonstrated The facts seem to place vitamin C in a somewhat different category from other substances of known physiological activity—for example, the hormones, thyroxine, and insulin seem to be present in all vertebrates The other vitamins seem to be pretty widely and evenly distributed, vitamin A can be found in almost any liver oil, B in most green vegetables, while D is formed when ultra-violet light acts upon a sterol, which again is widely distributed But vitamin C may be relatively abundant in one of two closely related fruits, and absent from another, notwithstanding *the fact that they are growing almost side* by side These rather remarkable facts recall to memory the fact that the incidence of scurvy is itself not so general as is that of other deficiency diseases Of all the common laboratory animals, the guinea-pig is the only one which is susceptible, and the only one, therefore, which can be used for experiments with vitamin C, of other animals, it seems that only man suffers from the disease It is possible that there may be here an interesting problem for geneticists It is impossible not to advert to the need, brought out very forcibly in the communication here discussed, for some method of assaying vitamin C other than that of animal experiment Vitamin A can now be estimated with some exactitude by means of a chemical reaction, but for all tests for vitamin C guinea-pigs have still to be employed, and the labour and expense entailed are very large indeed A large number of animals have to be used, and they must be kept under the very best conditions, not only for humanitarian reasons, but because relaxation of precautions inevitably renders all results worthless, through failure of the controls to behave normally or because of the incidence of intercurrent disease It is interesting that, in this work, it has been found possible to avoid gastro-intestinal epidemics by the use of prophylactic vaccines

A STATISTICAL STUDY OF ALCOHOLISM

SOME interesting facts about 1,645 patients consecutively discharged from Dalrymple House, Pickmansworth (an institution for the treatment of men of the educated class suffering from alcohol or drug excess) are set out in tabular form in an appendix to the medical superintendent's report for 1929–30 Only forty seven of the patients suffered from drug addiction alone, but of the rest over 200 took drugs in some form or other morphine and opium addiction being commonest, and addiction to cocaine, though much rarer, next Most of the patients are described as having social habits, only seventy-five being of the solitary kind Their temperaments are classified in the tables under the headings nervous nervo-sanguine, passionate phlegmatic, and sanguine the majority (993) being of the first type, 256 of the last, and only 33 being described as passionate Fifty per cent of the patients gave a family history of inebriety, and 11 per cent of insanity with or without inebriety In 1,104 the drinking habits were regular, in 495 they were periodical, the frequency of bouts ranging from once a week to once every twelve months Delirium tremens attacked 429 patients, of whom 258 had one attack 119 two, 26 three, and so up the scale, ending with 13 patients who had had twelve attacks The age period of greatest addiction was 30 to 40, with 636 patients though the period 40 to 50 ran it close with 504 One of the patients was under 20 and four were between 70 and 80 Over half the patients (856) were married 110 were widowed, and 679 were single *A study of the occupations* suggests that the greatest susceptibility is among persons with no occupation the number in this group being 320 next in order come merchants (178) and medical practitioners (130) There were only twenty-two persons in the group classed as artists and theatrical Influence of occupation is suggested as an exciting cause in 115 cases, including commercial travelling in 14 journalism in 9 and wine and beer trade in 33 Other prominent exciting causes are sociability in 202 cases overwork in 77, and nervous shock—a wide term including war service domestic trouble business worry, and financial loss—in 295 Prominent among the complicating diseases were alcoholic neuritis (77) chronic constipation (57) general debility (56), morbus cordis (47), renal disease (48), chronic rheumatism (27), and syphilis (32) The average

length of the period of treatment was twenty and a half weeks, the after-histories of the patients being as follows abstaining 40 per cent, improved 6 per cent, not improved 22 per cent, insane 2 per cent, no news obtainable or dead 22 per cent, and discharged unsuitable for treatment or transferred elsewhere 6 per cent

MELBOURNE HOSPITAL CLINICAL REPORTS

A new medical periodical, the *Melbourne Hospital Clinical Reports*, has now been established in order to obtain a wider circulation for the clinical and experimental work carried on at that institution, it will be published twice yearly, in June and November, under the editorship of Dr S O Cowen Two years ago special staff meetings were instituted for the discussion of medical, surgical, and pathological topics, and the opening papers, which were often based on analyses of the hospital case notes, have proved sufficiently valuable to merit permanent recording Certain senior members of the hospital staff have also been engaged in collecting and publishing historical records and reminiscences, and information of this nature will be included The first issue of the *Clinical Reports* opens with an attractive account of the history of the Melbourne Hospital, which has been prepared by Dr G T Howard, and it is announced that Sir James Barrett will contribute to the November issue some details of the progress of the institution from 1879 to 1883 The hospital was founded as long ago as 1834, but its growth was slow at first Quite a small building sufficed until 1852, when the great influx to the gold diggings led to a series of increases in patients and buildings which brought the accommodation up to about 300 in 1867 The present buildings, opened in 1913, provide a total of 414 beds, and last year 8,400 in-patients were admitted and 57,000 out-patients were treated The clinical records in this first issue include an account of focal infection, by Dr C H Kellaway, director of the Hall Institute of Research, and F Eleanor Williams Drs H F Maudsley and R J Wright-Smith describe a case of encephalitis periaxalis diffusa, Dr K D Fairley discusses the diagnosis and prognosis of complete blocking of the right branch of the bundle of His, and also comments on the value of laboratory aids in the diagnosis of hydatid disease The opening paper read by Dr L E Hurley at a staff discussion on diabetic coma, is printed, it was based on an analysis of fifteen cases unaccompanied by surgical complications, and some practical considerations in the treatment of this condition are appended Other articles relate to the treatment of furunculosis by x rays, and the diagnosis of thrombo-angiitis obliterans Dr R J Wright-Smith, pathologist to the hospital, describes certain museum specimens Miscellaneous case reports complete an interesting record of clinical work, the compilation of which promises well for the future success of the new periodical

MEDICAL APHORISMS OF CORVISART

IT is probably true that every thoughtful practitioner of medicine, almost insensibly perhaps, accumulates from his own experience a more or less numerous series of guiding propositions which hold his faith and direct his path Some of these, were they published, would be valuable contributions to the art of medicine To be successful, however, such an enterprise makes a high demand, it claims both deliberation and confidence and some capacity for literary effectiveness, and these virtues are not every man's property Yet when they are set to the purpose the result is both attractive and serviceable Such terms of appreciation may justly be applied to the recently published volume of *Aphorismes de Medecine Clinique par le Baron Corvisart* [1]

[1] *Aphorismes de Médecine Clinique par le Baron Corvisart* Recueillis par F V Mérat Publiés par le Dr Paul Busquet. Paris Masson et Cie (20 fr)

The collection has an interesting history It was recently discovered in manuscript together with a note explaining that the author had not found the opportunity to publish it because of the duties imposed upon him as Premier Medecin de l'Empereur Napoleon The discovery is certainly a welcome one, and we are indebted to our French colleagues for an opportunity of studying the medical aphorism as this may be constructed by a master of the art and expressed in a language peculiarly capable of the effective phrase Our readers bent on holiday plans may perhaps be inclined for literature outside the professional bookshelf, yet if they enjoy deliberate and well-balanced judgements presented with artistic point and force they will find Baron Corvisart's aphorisms excellent company, and to examine them in the light of an added century of observation and discovery is an inviting opportunity for thought and criticism Dr Paul Busquet, who has edited the volume, introduces with a brief commentary each of the four groups in which the sentences are arranged and his notes have a distinct interest It must certainly be allowed, as Dr Busquet claims, that the aphorisms show the author to have been not only a physician of wide knowledge and great distinction, but devoted also to the highest standards of professional duty and responsibility His teaching relates both to the technical art of medicine and to the mental and moral attitudes to be cultivated by the practitioner, and always his point goes home To select particular sentences for quotation is to become sensible of an embarrassment of riches, but we can hardly resist "Le Medecin doit bien se garder de la manie de tout expliquer", and there are many others of equal temper and point

MEDICAL INSURANCE AGENCY

A MEETING of the committee of management of the Medical Insurance Agency, Limited (by Guarantee) was held at the House of the British Medical Association on July 29th, when the report of the twenty-third year of the agency's work and the corresponding balance sheet were adopted Although the prevalent commercial insecurity in the country must have had a depressing effect on the agency, yet it was revealed in the report that the general progress of previous years had satisfactorily continued, an outstanding feature being the opening of the office in Scotland, where the volume of business dealt with had been highly gratifying The total premium income for the year approximated £98,000, an increase of more than £8,000 as compared with the previous year The amount of business now passing through the agency may be gauged from the fact that no fewer than 6 500 renewals had to be dealt with The commission from motor-car insurance continued to increase rapidly, and is a practical proof of the satisfaction caused by the special policy for medical practitioners In last year's report it was mentioned that life assurance, etc, dealt with through the agency approximated a total of one and three-quarter million pounds, during the year now under review the figure rose to two million pounds The following grants were made to organized medical charities for 1930

		£	s	d
Royal Medical Benevolent Fund		630	0	0
Royal Medical Benevolent Fund Guild		630	0	0
Epsom College—				
Dawson Williams Memorial Fund	£650			
Royal Medical Foundation	£210			
Head Master's Distribution Fund	£100			
		960	0	0
Girls' Education Fund		250	0	0
Royal Home for Incurables, Putney		52	10	0
Sir Charles Hastings Fund		52	10	0
Royal Medical Benevolent Fund (Ireland)		25	0	0
		£2,600	0	0

As a result of this distribution the total sum devoted to medical charities by the Medical Insurance Agency since 1910 has amounted to £25,580

MATERNAL MORTALITY AND MORBIDITY

THE DEPARTMENTAL COMMITTEE'S REPORT

THE interim report of the Departmental Committee of the Ministry of Health on Maternal Mortality and Morbidity has been somewhat impatiently awaited It was published this week, and proves to be an extremely interesting and important document, which fully justifies the apparent delay for which the committee under the chairmanship of Sir George Newman has in some quarters been blamed Some measure of its importance is indicated in a leading article this week at page 218, but there are so many weighty matters dealt with in its 151 pages that a careful study of them must be advised

The committee desired to base its report upon an examination of a sufficient number of maternal deaths of which reports had been made by an experienced medical officer in each sanitary area in accordance with an arrangement entered into in the early part of 1928 The draft form of inquiry in connexion with this arrangement, which received the concurrence of the British Medical Association under conditions safeguarding the confidential nature of replies thereto, was issued in October of that year, and the main part of the departmental committee's report is based upon a careful examination of the first two thousand cases of which particulars have thus been obtained Although at the present time about two-thirds of all maternal deaths in England and Wales are coming under the notice of the committee, in the earlier months the returns were not so abundant, and a considerable time has had to elapse before a sufficient amount of material could be accumulated, examined, and analysed

Though some of its sections may be regarded as complete the report is an interim report, since the committee say "We propose to reserve for a subsequent report further inquiries and recommendations concerning morbidity associated with pregnancy and the puerperium, puerperal sepsis, statistical aspects of the maternal mortality rate, methods of public education in the preventive side of the problem, and some outstanding questions involving research in which we are now engaged, together with an account of our investigation into an additional number of maternal deaths" It will be remembered that Mr Neville Chamberlain, as Minister of Health, had appointed another departmental committee, under the chairmanship of Sir Robert Bolam, to report mainly on the training and employment of midwives The report of that committee was noticed at some length in the *Journal* of September 28th, 1929 (p 592) The references to the two committees allowed of some overlapping in the present report some matters concerning the training of midwives in relation to that of medical students in maternity wards or hospitals, and the position of midwives in a national maternity service, are dealt with from a somewhat different point of view, but with general agreement

Investigation of Maternal Deaths

The two thousand maternal deaths which were investigated were unselected cases, probably representative of the deaths occurring all over the country They are classified in a way which has much practical value, and the conclusions which are drawn from them are expressed very carefully and with a commendable absence of dogmatism The two main classes are (1) deaths directly due to pregnancy and child bearing, including abortion and ectopic gestation (1,596), and (2) deaths due to an independent disease concurrent with pregnancy or childbirth (404) In the first class 38 6 per cent of the deaths were due to sepsis, and 13 6 to eclampsia, while shock antepartum and post-partum haemorrhage, other toxaemias and embolism were responsible severally for percentages varying between 6 and 9 The 616 deaths from sepsis have been divided into three classes (1) following ordinary normal labour, (2) following delivery by low forceps in an otherwise normal labour and (3) following complicated labour The numbers in these groups were 294, 47, and 275 respectively The main object of this investigation was, of course, not academic but practical The investigators have accordingly tried to discover in each case what they call the "primary avoidable factor"—that is, the first omission, mistake, or misjudgement in the train of events which led up to the fatal result, the standard of comparison on which judgement was based is set out It is not an unduly high one, but rather one which may reasonably be expected to be attained in good medical practice in most parts of the country Omitting cases of abortion and of extrauterine gestation and a number of others in which information was insufficient, the cases which showed a primary avoidable factor were 626, and those in which no departure from established practice having a causal relationship with the death was found were 659 In a broad general analysis, therefore, and with no claim to mathematical accuracy, it may be said that the net percentage of preventable deaths is as high as 48 The primary avoidable factors in these 626 cases are subdivided under four headings (1) omission or inadequacy of ante-natal examination (226), (2) error of judgement in management (224) (3) lack of reasonable facilities (64), (4) negligence of the patient or her friends—usually in failing to follow the doctor's advice or in ignoring obvious and serious symptoms—(112) In the first two of these groups the doctor, the midwife, the hospital, or the clinic may have been at fault, and the first group contains 109 cases in which the pregnant woman did not submit to ante-natal examination These are not included in group (4)

The committee realizes that "caution must be exercised in drawing conclusions from the evidence obtained from these investigations," but it is clear that information has been elicited which is of definite and substantial practical value The vast importance of adequate ante-natal examination and supervision in *every* case is reaffirmed, and adequate treatment of any discovered abnormality should naturally, but does not always follow Further, in relation to serious complications and accidents of labour, whether or not they might have been foreseen and averted by ante natal care the committee have ample proof of the need for a higher standard of knowledge and skill on the part of the *general practitioner* as well as for the provision of consultant services and of an increased number of readily available hospital beds Amongst the death from haemorrhage a number of patients might have been saved had specialist services (including facilities for blood transfusion) been at hand At the same time it must not be lost sight of that the majority of cases of haemorrhage and obstetric shock can be saved from death by the immediate replacement of fluid by intravenous or subcutaneous saline solution" Attention is drawn to the relative infrequency with which this treatment is administered With regard to sepsis, substantial improvement may be looked for when ante-natal diagnosis becomes more efficient and widespread when a specialist service is more easily obtainable and when hospital accommodation for suitable cases is more adequate Even so, the number of deaths from sepsis following "normal labour" demands intensive investigation

Puerperal Sepsis

In view of its importance this matter of puerperal sepsis is dealt with in a separate chapter of the report It is considered in its administrative aspect in regard to its causes both bacteriological and predisposing and whether the microbic infection is extrinsic or in origin with reference to its prevention by method of sterilization and by the proper construction equipment and staffing of maternity institutions and in relation to its treatment A number of very valuable suggestions are incorporated in this chapter and in an appendix on sterilization of the hands by Dr Leonard Colebrook Among other matters discussed are the unreliability of lysol, the use of gloves and of masks and the need for the provision of sterilized pads and swabs It is stated that investigations into the value of certain methods of treatment will be summarized in the final report

[1] Ministry of Health Interim Report of Departmental Committee on Maternal Mortality and Morbidity London H.M. Stationery Office 1930. (2s. net.)

Ante-natal Care

In the chapter on ante-natal care the pioneer work of Dr J W Ballantyne is acknowledged, and reference is made to the committee's "Memorandum on ante-natal clinics, their conduct and scope," which was issued to local authorities by the Ministry of Health in July last year This is now reprinted as an appendix to the report We commented upon it shortly after its publication (*Journal*, August 17th, 1929, p 315) Some amplifications of this memorandum are made in the chapter, but nothing very material is added The prime importance of the clinics when properly conducted, for the education of the pregnant woman, of the midwife, and, when in suitable association with a teaching hospital, of the medical student is fully recognized, as is also the possibility that in other respects they may supply a need which is only temporary "Under a reformed maternity service much of the work of routine examination clinics may be transferred to the family practitioner and the trained efficient midwife, but at present they are essential for securing ante-natal care when it would not otherwise be available" The different functions of the true consulting clinic are pointed out, and an important statement, to which the attention of local authorities and their officers may again be drawn, is that "generally speaking, treatment of abnormal cases is not the work of an ante-natal clinic" In paragraph 177 of a subsequent chapter the committee emphasizes this, and enunciates "that it is a principle to be acted upon, wherever possible, that the person responsible for ante-natal supervision should be responsible for attendance during labour", and in paragraph 174 it gives reasons why this attendant should be the ordinary medical practitioner and not one of a "selected panel," whether whole-time or part-time

Anæsthetics in Obstetrical Practice

Other very important and valuable chapters of the report deal with the use of anæsthetics and analgesics in obstetric practice, with medical education in obstetrics, and with a national maternity service On the first of these subjects three interesting memorandums are given in appendixes—one from the Royal College of Physicians of London, one from the British College of Obstetricians and Gynæcologists, and one from the British Medical Association This last is printed in the Annual Report of Council (*Supplement*, April 19th, p 163), and was approved by the Representative Body last month It is perhaps the most emphatic of the three with regard to the use of anæsthetics and analgesics by anyone other than a registered medical practitioner, but the three pronouncements are in substantial agreement, and the committee does not differ from them in their conclusions

Medical Education

In regard to medical education, the most important suggestions of the committee are (1) that the statements of the requirements of the General Medical Council should be made more clear and definite, (2) that the time given to midwifery and gynæcology (including infant hygiene) should be doubled—six months' whole-time hospital practice, including two months' residence in a maternity hospital, (3) that the number of labour cases personally attended (in the suggested alteration "attend and personally deliver") shall be thirty instead of twenty, (4) that ante-natal instruction shall entail the personal examination, under supervision, of not less than fifty pregnant women, (5) that there shall be at least eight attendances at an infant welfare centre, (6) that priority shall be given to the medical student over the student midwife in maternity hospitals, or possibly that students and midwives shall be educated together in this respect

Training of Midwives

The committee had before it the proposals which the British Medical Association was the first to make in any detail for a national maternity service, together with other subsequent and somewhat similar proposals made by the Departmental Committee on the Training and Employment of Midwives, by the Medical Women's Federation, and by others The first of these has been issued separately as an Association document, and is now well known The various schemes do not differ in essential respects, and the principles on which they are based and the requirements which they should embody are set out and endorsed by the committee In a few respects the present report carries the suggestions somewhat further, and it may be noted that where in some minor points the schemes differ from one another it is to the British Medical Association's proposals that the committee more closely adheres It avoids, however—perhaps wisely in the circumstances—those very difficult administrative and financial aspects of the scheme to which the Association's document gives some attention

Another possibly wise feature of the report is that there are no definite recommendations tabulated at its conclusion This will possibly induce a larger number of those interested to read the whole of the body of the report, and with great advantage, for it contains much valuable information, many wise comments, and a large number of practical proposals

Scotland.

Lochaber Hospital Extension

THE Duke of York, on July 30th, inspected the new power works at Lochaber, one of the largest hydro-electrical schemes in the world, and visited the town of Inverlochy where the men employed at the works are accommodated, he also opened an extension of the Belford Hospital Cameron of Lochiel, chairman of the hospital trustees, presided, and mentioned that this hospital had been originally completed in 1864, it now received an annual grant of £200 from the Department of Health, as well as a large contribution each year from the British Aluminium Company For the past two or three years it had been realized that the hospital was in urgent need of reconstruction, and a sum of £4,500 had been raised for the present extension, which included a new operating theatre The extension was intended to commemorate the late Dr Cameron Miller, who had been greatly beloved in the district The Mackintosh of Mackintosh paid a tribute to the memory of Dr Miller, who, he said, had never spared himself, it was possible that his war work and the strenuous duties in connexion with the power scheme had combined to shorten his life The Duke of York afterwards declared the extension opened and unveiled a plaque at the entrance of the operating theatre which bears the following inscription "This operating theatre was erected to the memory of Alexander Cameron Miller, M D, Ch M, F R S E, T D Born, 12th August, 1861, Died, 31st December, 1927 For 41 years Medical Superintendent of this Hospital, beloved physician of the people of Lochaber *Dileas Gu Bas*"

Memorial to the late Dr Alexander Stuart

An extension to the Crieff and District Cottage Hospital, intended as a memorial to the late Dr Alexander Stuart, was opened on July 29th The extension was the gift of Mr W Gilchrist Macbeth of Dunira, who performed the opening ceremony The present extension consists of a solarium fitted with vita glass, enabling convalescent patients to be exposed to the sunlight in all conditions of weather There are eight beds and two cots In handing over the gift to the hospital trustees, Mr Macbeth paid a tribute to the valuable work performed in the Crieff district by Dr Stuart

Appointment for Edinburgh Radiologist

Dr J M Woodburn Morison, lecturer in radiology in the University of Edinburgh and radiologist to the Royal Infirmary of Edinburgh, has been appointed professor of radiology in the University of London, and medical director of the radiological department of the Cancer Hospital, Fulham, in succession to the late Dr Knox This is the first professorship of radiology to be established in this country Its duties include the practice of both radiology and radium therapy at the Cancer Hospital, Fulham, and the instruction of students in these subjects Dr Woodburn Morison is a native of Ayrshire After graduating

M.B. at Glasgow University in 1896, he became assistant radiologist to the Royal Infirmary of Manchester and consulting radiologist to the Ancoats Hospital, Manchester. He holds the diploma in radiology of the University of Cambridge, and has written much upon various aspects of the subject. Five years ago he was appointed radiologist to the Royal Infirmary of Edinburgh and lecturer in radiology to the University; recently he was elected a member of the Radium Commission and a member of the Radium Trust.

Central Midwives Board for Scotland

The examinations of the Central Midwives Board for Scotland held simultaneously in Edinburgh, Glasgow, Dundee and Aberdeen, have just concluded, with the following results. Out of 112 candidates who appeared for the examination 101 passed. Of the successful candidates, 28 were trained at the Royal Maternity Hospital, Glasgow, 24 at the Royal Maternity Hospital, Edinburgh, 5 at the Maternity Hospital, Aberdeen, 7 at the Royal Infirmary, Dundee, 16 at the Elsie Inglis Memorial Hospital, Edinburgh, 3 at Stobhill General Hospital, 2 at Barshaw Hospital, Paisley, 4 at the County and City of Perth Royal Infirmary, and the remainder at various other recognized institutions.

England and Wales

The Order of St. John and the British Red Cross Society

THE tenth report of the Joint Council of the Order of St. John of Jerusalem and the British Red Cross Society—the first to be issued from the new offices of the council at 12, Grosvenor Crescent—covers the period from January 1st to December 31st, 1929. The council records that the total number of patients assisted since the beginning of the war by the auxiliary hospitals for officers department is 18,028. The majority now receiving help are ex-officers suffering from tuberculosis. During the year assistance was given to 293 officers, 105 being new patients. Assistance included refunds to patients of hospital stoppages, allowances for special diet and convalescence, nursing home fees, and occasional contributions towards the cost of special appliances. In some cases full sanatorium fees were paid. Applications are now being made by officers who have allowed the official period of seven years since their demobilization to elapse before appealing to the Ministry of Pensions. Many of them have exhausted their private means in meeting the cost of treatment, and there is evidently little chance of their applications being favourably considered by the Ministry. Where full fees were paid the Officers' Association generally contributed half the amount. Eighty patients were admitted to the Hospital for Officers at Brighton, forty being sent by the Ministry of Pensions in the course of the year. In May, 1928, the Joint Council approved of a proposal that its hospital and medical services department should become a central bureau of hospital information under the auspices of the Joint Council and the British Hospitals Association. The success of the bureau is now regarded as assured. Through the close co-operation between the two associations the collecting of information has been greatly facilitated, especially as the offices of the bureau and of the British Hospitals Association are now in the same building. Much work was done by the bureau during the year in connexion with the effect of the Local Government Act on the voluntary hospitals. Its services were also sought in the distribution of funds of contributory schemes. As recorded in the tenth annual report of the voluntary hospitals in Great Britain (excluding London), the number of hospitals surveyed last year continues to increase. The necessary provision, however, of institutional treatment for sickness and accident, and the rapid growth of organizations in size and number, have made it desirable to have a wider and more comprehensive survey of every department of hospital work than is at present available. To meet this need a new year-book has been projected by the publishers of *Burdett's Hospitals and Charities*, which will extend the scope of that publication. In the arduous task of recording advances in the various branches of hospital activity the co-operation of the Joint Council and the British Hospitals Association has been obtained. Besides issuing memorandums on topics of special interest to hospitals the bureau undertakes to give advice in regard to sites for buildings, plans, etc., and prepares reports for committees of management. Among the philanthropic services organized by various committees the report mentions that over 5,000 Christmas gifts were provided on Christmas Day, 1929, for ex-service pensioner patients in Ministry of Pensions hospitals and similar institutions, and that more than 14,000 ex-service pensioner patients in hospital were given motor drives or conveyed to entertainments and theatres during the year. The Emergency Help Committee continued to provide relief to thousands of sick and disabled ex-service men and their dependants. The total number of new cases assisted or otherwise dealt with, during 1929 was about 23,000. Expenditure on grants for relief amounted to £60,926—£20,000 less than the figure for the previous year. It is satisfactory to note that £6,846 was received in voluntary refund of advances. This department also deals with applications from severely disabled pensioners to provide motor attachments for the tricycles supplied to them by the Ministry of Pensions. Since this work was undertaken in 1924 nearly 500 men have been loaned motors, which many of them use to travel daily to and from their work. In response to applications from Ministry of Pensions hospitals and other institutions treating ex-service pensioner patients, the Games and Comforts Fund made 343 grants of additional comforts and articles of recreation. The extensive and valuable work of the Home Ambulance Service has been recently referred to in these columns, particularly in connexion with road accidents. During the year the ambulances carried over 113,000 patients. A satisfactory report is given of the stores department which not only supplies such articles as are required, but gives expert advice of the most suitable market for direct purchases. During armistice week articles made by patients in hospitals in London and in the provinces were displayed as part of the exhibition and sale of ex-service men's work at the Imperial Institute. Grants for ward industries were given to ten hospitals last year, seven of these were Ministry of Pensions institutions. The Finance Committee reports that the expenditure for the year exceeded the income by £1,780, which compares with a deficit of £814 for the previous year. The Joint Council expresses the hope that its income will increase with improvement in industrial conditions.

Local Authorities and Cancer Research

The seventh of a series of memorandums relating to the causation, prevention, and treatment of cancer has now been issued by the Ministry of Health, accompanied by an explanatory circular (No. 1136). The present memorandum indicates how local authorities may take steps to obtain more complete knowledge of the reactions between cancer and the community, thereby rendering it possible to bring into effect local ameliorative measures. The Minister invites the councils of counties and county boroughs to consider the initiation in their areas of an attempt to ascertain the ways in which the environmental, economic, social, or other conditions of cancer patient affect their chances of cure and relief of suffering. Contact with patients would in the first instance be limited to those applying for treatment at the local hospitals, and in friendly collaboration with the medical staff a series of questions is suggested in order to indicate the general lines upon which the early investigations might proceed. It is thought that the essential information could be obtained through the agency of suitable non-medical members of the staff of a health department working under the fairly close supervision of a medical officer. As the result of analysing a collected sample of individual histories obtained in this way local authorities might find it possible to improve the lot of cancer patients in their areas by giving individual advice and help, and by improving the existing facilities for dealing with the disease or devising new ones. Mention is made of the collective investigation into the incidence of cancer and its history

after treatment which was initiated by the British Medical Association and the belief is expressed that the new inquiry would dovetail conveniently with this, both being benefited thereby Attention is drawn to the advantages to be gained by co-operation between medical officers of health and the Departmental Committee on Cancer

India.

Hospitals and Dispensaries in the Central Provinces and Berar

A policy of progress and expansion in the provision of medical relief is outlined by Colonel W V Coppinger, I M S, Inspector-General of Civil Hospitals, in his report on the hospitals and dispensaries of the Central Provinces and Berar for the triennium which ended in December, 1928 At that date the number of dispensaries had increased from 303 at the close of the previous triennium to 335, and these services were supplemented by ten "cheap plan" dispensaries and thirty-nine travelling dispensaries controlled by the director of public health Several local bodies had taken advantage of the scheme of "cheap plan" dispensaries for which the Government provides the staff and one-fourth of the recurring expenditure, the remaining amount being raised by the local body concerned Travelling dispensaries, which were steadily gaining popularity, were found particularly useful in distributing quinine to patients in malarial districts As the Victoria Hospital at Jubbulpore and the main hospital at Raipur have become Government institutions, there is now, with one exception, a large and fully equipped Government hospital in every division in the province The Irwin Hospital, which has replaced the main hospital at Amraoti, was opened by the Viceroy in 1928 Other medical buildings constructed during the triennium included two new hospitals for women One of the principal features of the report is the provision of medical aid for women by women doctors Eleven women assistant surgeons and eleven assistant medical officers were attached to district and other important hospitals in areas where no separate women's hospitals had been established These appointments were made in pursuance of the Government's policy to provide a woman doctor at one town in every district No reluctance has been shown by the public in taking advantage of these developments The percentage of women treated in the Dufferin hospitals rose from 13 2 (in 1925) to 17 5 An increase of 8,000 in the number of in-patients is recorded, and, although 254 beds were added during the triennium, arrangements were being made at the date of the report to extend the accommodation in several of the main hospitals The expansion in the adult services has been accompanied by a more widespread recognition of the importance of child welfare Health propaganda was carried out in towns and schools by medical officers in charge of all the outlying dispensaries Progress in all these departments has been hampered, however, by an inadequate supply of trained nurses for both private and hospital patients even the best hospitals apparently were unable to provide first-class nursing The provision aimed at is one nurse to every five beds in general hospitals, and one to three beds in women's hospitals At the Victoria Hospital, Jubbulpore, there were only four nurses for 105 beds The whole question of the organization and training of nurses was being considered by the Government when the present report was issued Another problem was the treatment of patients in rural areas Since the close of the triennium a scheme has been put into operation for subsidizing private practitioners who consent to settle in approved centres The Government has also sanctioned the institution of ten scholarships of Rs 20 a month for study at Benares University with the object of encouraging practitioners possessing recognized qualifications to improve the indigenous systems of medicine In order that rural areas should ultimately receive the benefit of these provisions it is proposed to make grants in aid to local bodies up to half the expenditure incurred by them on this account, subject to suitable conditions Large grants have already been allocated for the study and treatment of leprosy in the province In 1928 treatment was given to 1,459 lepers, compared with 1,051 in the previous year, the increase is attributed mainly to effective propaganda One specialist and twenty assistant medical officers have been appointed for leprosy work in Chhattisgarh, the method employed of visiting lepers in or near their homes and establishing treatment centres in selected areas is expected to produce better results than the policy of segregation At the treatment centre at Khot one hundred lepers attended twice a week from the neighbouring villages Seven leprosy clinics have been opened at the headquarters of seven districts, moreover, the accommodation in the eight leper asylums is being gradually increased

Medical Facilities in Bihar and Orissa.

A critical period in the development of medical policy in Bihar and Orissa is indicated in the triennial report of the hospitals and dispensaries in that province for the years 1926-28 The ideal aimed at is the provision of a dispensary in every police station area, so that treatment may be available for any sick person within a distance of five miles Although this ideal had not been attained in any district at the date of the report, a considerable expansion is recorded in the general facilities for medical relief eighty-two new hospitals and dispensaries having been opened during the triennium In many districts, however, the expenditure incurred for this purpose exceeded the minimum sum laid down by statute, in spite of augmented Government grants One reason appears to be a persistent indifference towards the financial needs of local hospitals no increase is reported in charitable contributions This attitude is attributed partly to the fact that the public is inclined to regard medical relief as one of the returns expected from taxation, and partly to the widely recognized practice of the comparatively well-to-do of seeking free treatment at charitable institutions Proposals for authorizing hospital committees to impose small fees on these patients were under the consideration of the Government The report states that such continued indifference is likely to threaten future progress, especially since all the large hospitals in the province are now dependent on Government support, formerly, as local board institutions they were directly supported by local funds Another aspect of medical relief, referred to by Colonel W S Willmore, I M S, Inspector-General of Civil Hospitals in the province, is the necessity for setting a limit to the amount of work that can be efficiently carried out by medical officers Undue attention, he thinks, has hitherto been paid to the amount of work undertaken in dispensaries, without adequate regard for the efficiency of the treatment This tendency in his opinion must impair the prestige of medical science as practised in the West, particularly as it is being brought more and more into competition with the indigenous systems of medicine In this connexion an outstanding problem in the province has been the provision of medical aid to women, not only on account of the deficiency in the supply of women doctors, nurses, and trained midwives, and the reluctance that exists among certain classes to accept the services of male doctors, but also because most women, influenced by custom and prejudice, have been unwilling to take up medicine and nursing as professions At the date of the report not a single woman had applied for admission to the medical college, and only five were attending the medical school at Cuttack No private nursing homes were available in the province, and there appear to have been very few private nurses Apart from the financial difficulties involved in the duplication of staff, the only permanent solution seems to be the gradual removal of restrictive codes In this matter some headway is reported to have been made during the last year of the triennium A great deal of medical relief however, was provided for women of the humbler classes The number treated as out-patients in 1928—although only a third of the number of men—was over 9 million, while the number of in-patients increased from 6,000 to 15,000 since the constitution of the province Notable progress is also recorded in maternity and child welfare In Patna, for example, no deaths from tetanus

or sepsis had occurred for over five years among the patients who were under the care of the maternity supervisor and her staff Several special institutions, established in the province during the triennium, are described in the report, including a sanatorium for tuberculous patients at Ithri, a Pasteur Institute at Patna and a bacteriological laboratory at the Patna Medical College The transfer of the Radium Institute from Ranchi to Patna Medical College Hospital has greatly extended the scope of *radium treatment and provided* valuable opportunities for study and instruction A campaign has been instituted against leprosy, and large sums are being spent on segregation and treatment

Correspondence.

OBSERVATION AND EXPERIMENT

SIR,—No one can have read Mr Wilfred Trotter's essay in the *Journal* of July 26th without being grateful to him for such an illuminating presentation of the methods of investigation, and without being stimulated by it Nor can anyone fail to realize how important it is that we should grasp the *essential truths that he* unfolds before us It is at the same time somewhat depressing to find that in the hierarchy of endeavour such a lowly place is given to clinical observation, and I cannot help wondering whether the melancholy with which he recognizes the necessity for a genius and a special aptitude of mind, if advance is to be made along these *lines, is completely justified It may be so at the moment,* but need it be so for the future?

I am among those who think that the pendulum has swung somewhat too far away from clinical observation, particularly where the teaching of students is concerned In these days of short cuts and labour-saving devices I cannot help thinking that the methods of careful observation, reflection, and deduction, if properly inculcated, would not only ensure a habit of mind attuned to the reception of new ideas, but might also provide a vast army of workers eager to obtain from their clinical material some clue to the mysteries that surround so many aspects of disease

I am certainly in agreement with the view that the production of a mass of statistics is largely valueless, and that haphazard observation as a bolster to *a priori* conclusions may be sterile, but it should be our endeavour to provide the possibility of a more enlightened form of research and to train more carefully the workers of the future

The human body in health and disease is both our raw material and our laboratory, its reactions to environment, to infection, and to mutilation provide the problems that we have to solve Who is so fitted to find out what these problems really are as the skilled clinical observer, and who is more likely to direct the investigation along the right lines? His own observations need not be entirely without result if they are conducted with an inquiring mind The path may be long, the progress is necessarily slow, and the difficulties are great, but the fact that they are somebody's symptoms which we are studying need not destroy their value as material for science

As a surgeon I can, for instance, study nature's effort at repair, and perhaps wonder why when one has removed large portions of the skull in the checking of an osteomyelitis new protective bone is so quickly formed, while after a submucous resection of the septum there is apparently *no attempt at the regeneration of the cartilage* removed Or, again, I may observe that radium will destroy completely a cancer of the tonsil, and yet seem to drive the cancer cells to some more distant spot with the formation of a growth in this new situation Again I wonder why and to wonder sufficiently is halfway to finding out We all have a sufficiency of material to our hands and no one is so busy that he cannot think if he trains himself to do so In time experience comes, and *experience* does not only teach, it also performs Who can tell what far-reaching results such performance may reveal?

We should be thankful for every new method of investigation, and I would have the clinical observer employ every weapon that has been forged for his use but I will not despair of result or lose my hope that clinical observation will remain the living root of our tree of knowledge —I am, etc,

London W 1 July 29th WILFRED HOWARTH

SIR,—Mr Wilfred Trotter's article in the *Journal* of July 26th contains an admirable appreciation of the relative merits and shortcomings of the experimental and the clinical methods in the study of disease It balances them more evenly than Sir Thomas Lewis's recent contribution on the same subject appeared to do Although Mr Trotter does not mention it specifically, there is one region of medicine in which the clinical method has superior advantages, and must remain, at least for a long time, the principal method of research, I mean the region of psychological medicine Here the subject-matter is the whole man, as a social unit, and the opportunities of arranging the conditions in the manner of an experiment are exceedingly rare

It is necessary, moreover, to distinguish an intermediate method of investigation, between the purely *experimental method on the one hand* and the purely clinical on the other, I refer to the introduction into clinical work of instruments of precision, which serve to give an air of scientific accuracy (often a spurious air, it is true) to clinical research The sphygmomanometer and the haemocytometer are examples of these instruments, and they are often helpful, but in psychological medicine *importations of this kind from the experimental field* are wanting in usefulness The psychogalvanometer so-called, is of sadly little service There is no instrument yet devised that can read a man's thoughts or ascertain his motives

There is, of course, a large variety of mental syndromes of the organic reaction type, for which biochemistry and histopathology offer approximately causal explanations But far more numerous in practice are the psychoneuroses and the psychoses the most important of which have no causally significant physical concomitants The advances made by the clinical method applied to these groups in the last thirty years have often been brilliant while the assaults made from the laboratory and more experimental side, although very numerous have as a rule been *comparatively unavailing There is real promise in Pavlov's* work, but here the gap between animal experiments and clinical observation is at its widest, and facile analogy is peculiarly misleading

A plea based on these considerations may well be made, especially in this country, for the intensive clinical study of mental illness, both inside and outside of asylums for the clinical method in this field is not only intensely interesting in itself, but unrivalled for the understanding of the mental conditions in question It is true that a special type of clinical observer succeeds best in this the type often called intuitive But it seems likely that clinical intuition, here as elsewhere, is simply the result of long study of human nature organized by long practice and operating largely unconsciously *The triumphs of* intuition in psychological *medicine are probably therefore* essentially the fruits of the observational method —I am, etc,

London W 1, July 30th R D GILLESPIE

PARTURITION AND PHYSICAL TOIL

SIR,—This is the season when the medical profession is wont to write articles for the newspapers warning holiday-makers against the dangers of unaccustomed exertion He teaches in effect the impossibility of performing hard work without suffering for it unless one has previously undergone a course of training to fit one for hard work I suggest that parturition is hard physical labour, not to be performed without undue exhaustion unless the woman is capable of hard work Women of the working class for example, are always kept in training for hard physical work by their daily round of toil, whereas women of the upper class are not, such differences of "training"

determine, I think, those differences of "fibre" on which the gynæcologist is apt to reflect

In India coolie women do much of the carrying when canals are dug or railways are built, and I have been told by those who have been in charge of such operations that it was quite usual for a coolie woman to work until the actual onset of parturition, and to return to work again immediately after the act was over I take it that parturition is a simple process for these women simply because they are kept in such perfect training for hard physical work If this is correct some of the present-day care of pregnant women seems misdirected effort They ought not to cease physical labour well before their due time, but, on the contrary, keep at work or in training, right up to the actual event In making the suggestion I am well aware of the *post hoc propter hoc* argument which would make some form of heavy lifting precipitate labour, but I do not know if it has yet been shown that physical work can precipitate labour in a woman entirely free from luetic taint Indeed, if hard physical work had any regular definite influence in precipitating labour the vast majority of women in this world should miscarry On the other hand, it may be that specific types of work have a precipitating action, whereas work *per se* has not if this is so, research might well be directed towards finding out if unfavourable types of work exist

Another point worth considering is the possible favourable influence of oxygen administration on women in labour who are not accustomed to hard physical work Physiologists have shown that an untrained man with the aid of oxygen can perform without undue fatigue work that would otherwise completely exhaust him and so, I take it, a woman should also be able to perform with the aid of oxygen, and without exhaustion work that would otherwise completely exhaust her It is also in the fitness of things that the untrained woman requiring oxygen could probably afford to pay for the extra"—I am, etc,

Lucknow July 4th W BURRIDGE

X-RAY TREATMENT OF TONSILS

SIR,—The letter from Dr Warner Collins on July 19th (p 122) should not be allowed to pass without challenge My plain statement (June 28th p 1197) of a "50 per cent or less of the erythema dose given in fortnightly or longer intervals" is travestied to imply that I give a "50 per cent erythema dose twice weekly"—that is, four or more times *the dose I use and recommend* May I repeat that there is no risk of dermatitis if accurately measured filtered doses are given as recommended? In young children 20 per cent doses, or in sun-sensitive adolescents or adults 30 per cent doses, may be found suitable, the patients, as always, must receive individualized treatment

I am astonished that Dr Collins can think a shrinkage to the normal size is "the greatest objection to the x-ray treatment" By pathological enlargement the mouths of the crypts are often blocked, and pus retention and swamping of the defence follow When the lymphoid substance is reduced the crypts open out, and all becomes "normal" The dosage is not sufficient to lead to fibrosis, as he wrongly infers Many patients after irradiation show a smooth, soft, supple tonsil surface with no visible crypts, others show flat gutter-shaped crypts in which no retention could take place Glands already hard and fibrous, following repeated suppurative attacks, give an incomplete response

As to the hypothetical damage to the thyroid and parathyroids by secondary rays, I have found that during a treatment, with the usual localized beam behind the angle of the jaw (projecting forwards, inwards, and upwards on to the tonsil and adenoid site), and the usual lead-rubber protection on the head and neck, there is no measurable pastille change (and only a slight dental film change) on the skin over the thyroid gland—that is, much less radiation than the thyroid receives during an x-ray exposure of the lower cervical spine Surely Dr Collins does not mean to assert that short x-ray diagnostic exposures "damage" normal organs or tissues, but this is what his statement about "secondary x-radiation" implies

As to antibodies being formed in the tonsils, the functions of the lymphatic glands as clearing agents for the tissues were well given as far back as 1911 in Lucas's *Physiology* (vol i, p 533) Later work on the reticulo-endothelial system has confirmed and elaborated these views Thus Aschoff, in his lecture on this subject published in 1924, says it is clear that bacterial toxins are fixed and absorbed, while antibodies are produced by the spleen and reticulo-endothelial system Topley and Wilson, in the chapter on the site of the formation of antibodies in their *Principles of Bacteriology and Immunity* write "The conclusions to be drawn do not seem to be in doubt there is ample evidence that the organs and cells, which have been shown to be concerned with the clearing mechanism of the tissues, are also concerned in some way with the formation of the sensitizing antibodies" In the next chapter they consider "local immunity" in a particular area such as the skin The latter theory may be still "sketchy in the extreme" but the general view as to antibodies being formed in lymphatic glands and other parts of the reticulo-endothelial system does not appear any longer to be questionable Moreover, the widespread development in mammals and birds of subepithelial lymphoid tissue just where bacteria most flourish (fauces, ileum and cæcum) shows its value as a defence mechanism

My views about the value of the tonsils were gained many years ago from Professor Lovell Gulland I am glad to find that there are now other supporters of his opinion as, for example, Professor Kenelm Digby in his *Immunity in Health* Mr Irwin Moore, in his *Tonsils and Adenoids* discusses the theories as to their function but ignores the recent literature on x-ray treatment Dr William Stewart appears to have been one of the first to treat patients with x rays (*British Medical Journal*, 1913, vol i, p 1157) Those who have followed the vicissitudes of medical fashions in history will not wonder at the slow progress of such a new and valuable conservative treatment, nor will they exclude the possibility that one day tonsillectomy may have as restricted a scope as blood-letting has now—I am etc,

J H DOUGLAS WEBSTER, M D,

London, W 1, July 26th

THE PERFORMANCE OF NECROPSIES BY GENERAL PRACTITIONERS

SIR,—Is it not time a period was put to the indiscriminate performance of post-mortem examinations by general practitioners at the command of coroners? As a rural practitioner I reluctantly undertake this task about once in two years, and I expect I possess about as much (or as little) knowledge of morbid anatomy as my brethren in similar circumstances, and I am getting a little exasperated at having to outrage my conscience every time I report on the cause of death As a student I performed the prescribed number of necropsies, and during two years as a house-surgeon in busy hospitals a considerable number of examinations fell to my lot But that is many years ago, and I have forgotten all about it One would not mind having a *large* number of post-mortem examinations to do, for then one could become proficient with some hope of remaining so, but I think the occasional necropsy by a general practitioner under the most adverse circumstances, with no facilities and with no skilled assistance, is a ghoulish farce which ought to cease

The coroners are not to blame They apparently are bound to ascertain the cause of death, and by hook or by crook they must extract it from the doctor Once, in a spasm of candour and honesty, I stated at an inquest that I had not the slightest idea what the individual whose corpse I had mutilated had died of The coroner commended my honesty, marvelled at the complexity of the problem, but pointed out that such high-souled ignorance was of no avail for his returns, and that if I could not give the exact cause of death I must give the most likely My pathological skill had reached so far as the detection of a few green peas in the stomach, and a few adroit questions of the "would it be in any way possible" order, resulted in the recording as my solemn opinion that

the deceased died of embarrassment of the heart caused by a surfeit of green peas! And yet the coroner and I were tolerably honest men, doing our best under rather difficult circumstances.

I think there is nothing to be gained and everything to be lost by professing a knowledge we do not possess, and unless I am a solitary monster of necrological ineptitude, there must be hundreds of practitioners who feel as I feel. Let it be freely admitted that morbid anatomy is a difficult and intricate art requiring constant exercise for its perfection, and that it is useless and unreasonable to expect any general practitioner chosen at random to possess or maintain the requisite skill. One might then be free from the nightmare of the ever possible 'cause célèbre,' with the carefully coached and politely ironical cross-examining counsel turning one's feeble post-mortem report into humorous copy for the sensational press.

Neither is there any need in these days of rapid communication, for the decencies of private life to be violated by these charnel house impromptus beneath stairs. Let there be central mortuaries in the sizeable towns with facilities for necropsies to be performed by those whose training or inclination tends that way, and let there be suitable conveyances for the speedy removal and return of bodies requiring such examination. I need not enlarge further upon the revolting aspects of private post-mortem examinations. They are distressing for the bereaved, embarrassing for the surgeon, and useless for the elucidation of the truth. I enclose my card, and remain, Sir, yours, etc.,

July 22nd. RESTICUS.

FIRST AID IN SERIOUS ACCIDENTS

SIR,—In nearly every account of a fatal accident nowadays, whether from motor, aeroplane, or whatever else, one reads, almost as a matter of course, the words "he died on the way to hospital." When a patient reaches our care after any "concussion" we enjoin complete rest of body and mind. Nature helps us by making the patient unconscious. Would it not be possible to educate the public and ambulance men to realize that complete rest is needed *at once*, and that the safest thing to do for a previously healthy person suffering from shock is to secure absolute quiet? If the constitution has been strong enough to resist a fall from the skies or the jarring of a collision, surely, if left alone, it may rally altogether. Fluid carried in a vessel rocks about, and the fluids in the ventricles of the heart and brain are surely rocked by the lifting, pulling, and "taking to hospital."

Should we not inaugurate a rule whereby the injured person is left where he lies until the medical man called in declares that it is comparatively safe to move him? Certainly these accidents often occur in places where the traffic may be impeded, but since we hold up traffic for a broken road, why not for a broken man?—I am, etc.,

Tunbridge Wells, July 31st. H. M. HENDERSON.

SPONTANEOUS SURGICAL EMPHYSEMA

SIR,—I have noted with interest certain references to cases of spontaneous surgical emphysema in recent issues of the *British Medical Journal*. While resident surgical officer at Ancoats Hospital I saw a man who had a very extensive emphysema, starting apparently in the neck and spreading, within the course of twelve hours, down below the nipple line. It followed on tooth extraction with a local anæsthetic, so that, as was suggested, any possibility of lung damage during the struggles of incomplete anæsthesia was excluded. The condition cleared up in the course of a few days without event, although the patient himself was considerably alarmed.

I can offer no explanation, and hesitate to postulate a similarity to cellulitis with gas formation; it is perhaps conceivable that a not very virulent organism might be capable of producing a considerable amount of gas.—I am, etc.,

London, July 26th. S. M. POWER, F.R.C.S.

Universities and Colleges

UNIVERSITY OF OXFORD

AT a congregation held on August 2nd the following medical degrees were conferred:

D.M.—F. Scott.

B.M.—W. D. T. Brunyate, L. R. Bowtell, A. Guirdham.

UNIVERSITY OF CAMBRIDGE

DR. G. H. F. NUTTALL has been re-elected to the Quick Professorship of Biology for one year from November 1st.

At a congregation held on August 2nd the following medical degrees were conferred:

M.D.—H. V. Dicks, G. W. Bamber.

M.B., B.Chir.—C. I. C. Gill, R. E. Parnsley, J. D. Simpson.

M.B.—E. A. Richards, E. J. Lee Smith, R. L. Osmaston, B. C. Tate.

M.B., B.Chir.—A. C. Crooke, H. W. Sadlier, R. S. Stacey, B. C. Nicholson, P. G. Levick, V. P. Paxon, I. J. Franklen Evans, J. S. S. Fairley.

By proxy.

UNIVERSITY OF LONDON

DR. J. M. W. Morrison, M.D. Glas., F.R.C.P.Ed. has been appointed to the University Chair of Radiology, tenable at the Cancer Hospital (Free). He is now lecturer in radiology at the University of Edinburgh.

Dr. W. Robson has been appointed to the Board of Examiners for the second medical examination, Part I., in the place of Dr. J. A. Hewitt who was unable to act through illness, and Mr. C. P. G. Wakeley has been appointed fifth examiner for the M.B., B.S. (surgery) examination, to act if required.

The regulations for the M.D. examination, Branch I. (Red Book, 1929-30, p. 193; Blue Book, September, 1929, p. 266), have been amended by the insertion after "A clinical examination" of the words "An oral examination at the bedside."

Dr. A. M. H. Gray has been appointed a member of the Finance and General Purposes Committee of the National Post-graduate School of Radiography.

Sir Cuthbert Wallace, K.C.M.G., has been elected chairman of the Research Funds Committee.

The annual reports of the superintendent of the Brown Animal Sanitary Institution for 1923 and 1929 record that during the former year 2,293 animals were brought to the institution and that in 1929 the number was 2,179. The five lectures required under the will of the late Mr. Brown had been delivered by the superintendent at the Royal College of Surgeons during December 1928 and 1929, the subjects of the lectures being respectively "The role of bacteria in Nature" and "The relation of pathogenic to saprophytic micro-organisms." Dr. Nathan Raw had continued his investigation on the attenuation of tubercle bacilli with special reference to the question of immunization against tuberculosis. Mr. Stauford Cade had carried out some experiments on rabbits with the object of testing the tolerance of the animals to solutions of colloidal bismuth with glucose, and to ascertain the relation between the weight of the animal and the amount of bismuth possible to inject intravenously. The experiments were a preliminary to some work to be done at Westminster Hospital in connexion with the radium treatment of cancer. The superintendent had continued his work on the ultra-microscopic viruses and on the essential substance, vitamin, obtained from acid-fast bacilli.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN

The following scholarships have been awarded for the session 1930-31:

St. Dunstan's Medical Exhibition, Miss J. W. Ellinger; Isabel Thorne Scholarship, Miss A. L. Mungrave; Sir Owen Roberts Memorial Scholarship, Miss F. C. Naish; Mabel Sharman Crawford Scholarship, Miss B. Clark; Alfred Langton Scholarship, Miss P. N. Greene; Ellen Walker Bursary, Miss S. W. Pyddoke; Flora Murray Bursary, Miss K. M. Jones; Special Bursaries awarded by Medical School, Miss B. D. Corner, Miss B. Hay Cooper, Miss M. H. Mayeur, Miss P. Wade; Julia Ann Hornblower Cock Post-Graduate Scholarship, Miss C. Day.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

A quarterly comitia of the Royal College of Physicians of London was held on July 31st, when the President, Sir John Rose-Bradford, was in the chair. The following Fellows of the College were elected officers for the ensuing year:—*Censors*, Frederick J. Poynton, M.D., W. Langlois Brown, M.D., Charles H. Box, M.D., Sir Charlton Briscoe, Bt., M.D., S. Isaac Elkan, M.D., Sir Humphry Rolleston, Bt., M.D., Robert O. T. H. Arnold Chaplin, M.D., Raymond Crawfurd, M.D.; *Treasurer*, Percy Moon, M.D.; *Registrar*, Hugh Jones, M.D.; *Librarian and Solicitor*, Sir Humphry Rolleston, Bt., M.D.; *Assistant Registrar*, Robert O. Moon, M.D.

Medals and Scholarships.

The Moxon Gold Medal, awarded every third year to the person who is deemed to have most distinguished himself by observation and research in clinical medicine, was awarded to Dr. Frederick Parkes Weber. The Weber Parkes Prize and Medal, awarded every third year for work on the etiology, prevention, or treatment of tuberculosis, were awarded to Dr. Ernest S. Lyle Cummins, C.B., C.M.G. The Morchi Scholarship was awarded after a competitive examination in clinical medicine to John St. Clair Likington, M.B., and Kenneth Moorhouse Robertson, M.B., jointly.

Harveian Oration and Bradshaw Lecture.

The President announced that he had appointed Dr. Percy Hamilton Ellison to deliver the Harveian Oration, and Dr. J. S. Fairbairn the Bradshaw Lecture in 1931.

Appointment of Representatives

Sir John Rose Bradford was appointed a representative of the College on a committee appointed by the Board of Control to advise on certain matters under the new Mental Treatment Act

Sir George Newman and Dr J W McNee were elected representatives of the College on the Executive Committee of the Imperial Cancer Research Fund

Dr A E Voelcker was appointed to represent the College at the celebration in October of the jubilee of the foundation of Mason Science College, Birmingham, and the thirtieth anniversary of the granting of the University charter

Lectures

The following acceptances of appointments were announced Dr Macdonald Critchley as Goulstonian Lecturer for 1931, Sir William Willcox as Lumleian Lecturer for 1931, Sir Andrew Balfour as Fitzpatrick Lecturer for 1931 Dr Samson Wright as Oliver Sharpey Lecturer for 1931, Dr J W McNee as Croonian Lecturer for 1932

Membership

The following candidates, having satisfied the Censors' Board, were admitted Members

Philip Jacob Alpers M B Melb Benjamin Barling M D Lond James Albert Brodrick M B Sydney James William Brown M D Lond Eleanor Mildred Creak M B Lond Philip Edwin James Cutting M D Lond John Dockray M B Camb Mohammed Abdul Aziz H Gammal L R C P John Cullis Hawksley M B Lond Roy Humphrey Howells M B New Zealand Charu Chandra Kapila M B Rangoon Gwash Lal M B Punjab Edward William Lindeck M B Camb Frederick Martin Lipscomb L R C P Florence Louis M B Lond Thomas Keith Sclfe Lyle M B Camb Harry Edward Mansell M B Oxon Dhirendra Chandra Mazumdar M B Allahabad Andrew John Morland M B Lond Santosh Kumar Mukhopadhyay M B Calcutta Margaret Geraldine Phoebe Reed M B Camb Edward Graeme Robertson M D Melb Gerald Richmond Anderdon de Montjoie Rudolf L R C P Ismail Ahmed Sabri M B Cairo James Dundas Simpson L R C P Eliot Trevor Oakeshott Slater L R C P John Smith M D Aberd Bashi Lal Taneja M B Punjab John Richard Hugh Towers M B Camb

Licence and Diplomas

Licences to practise physic were granted to 141 successful candidates, and Diplomas in Public Health Ophthalmic Medicine and Surgery, and in *Tropical Medicine and Hygiene* were conferred jointly with the Royal College of Surgeons (The lists of the successful candidates are published in the report of the meeting of the Royal College of Surgeons printed below)

The following diplomas were also conferred jointly with the Royal College of Surgeons

DIPLOMA IN LARYNGOLOGY AND OTOLOGY—C A Amesur A B Berkowitz I G Dermer A M H Hakim A H Sayed Handousa B Hillel I Kallmeyer F T Land M R Levey H Lewis G R Marcano I G Meade I Phillips S N Prasad H W Savage G S Seed S K Sen Gupta

DIPLOMA IN PSYCHOLOGICAL MEDICINE—R D Curran J W Fisher J Flind R N B McCord W M McGrath W Ogden D N Parfitt R Strom Olsen V Vassallo A W Watt

ROYAL COLLEGE OF SURGEONS OF ENGLAND

AN ordinary meeting of the Council of the Royal College of Surgeons of England was held on July 31st, with Lord Moynihan, the President, in the chair

Gold Medal

The honorary Gold Medal of the College was awarded to Mr R Lawford Knaggs, I R C S in appreciation of his services to the museum more especially in preparing a catalogue of and revising the Strangeways collection of specimens illustrating arthritis

Scholarship

The first Macloghlin scholarship for medical students was awarded to L J Honeywill of Bournemouth School

Examiners

Mr Frank Coleman *M C* dental surgeon to St Bartholomew's and the Royal Dental Hospital was elected a member of the Board of Examiners in Dental Surgery

Mr C H Fagge and Dr R G Canti were elected Examiners in Pathology under the Examining Board in England

Professors William Wright and C Lovatt Evans were nominated to conduct the primary examination for the Fellowship in Australia in 1931

Diplomas

Diplomas of Membership were granted to the following candidates, who had passed the final examination in medicine, surgery, and midwifery of the Examining Board in England

Constance F Allen S G Allen R E Angel Lily Arratoon J Azioun I G Badger W I Bain W L H L Bell S W T Bentall A C Bhardwaj I Billig W R Bion A N Birkett S Bochonek Kathleen M Bodkin B F M Bond E K Boston L V O Brown A Buch W R Burrows M L Bynoe L C Campbell G F Carey J Chamberlain H M Chappel L Charney W F Church L P Clarke A H Clegg D H Collins R V S Cooper W C Crosdeo R M S Cross Elizabeth T Davies L S Davies C G S De Silva C H Devin D Divine R H Dobbs J A Doherty N R Donald Mary G H Edwards A Elliott M M El Mishad A A G Flemming G M Flemming E V P Fox Margaret L Foxwell P I Franks L I Friedman Lorna M A Goulden Bach. The Services

DEATHS IN THE SERVICES

Surgeon Lieut Colonel James Anderson Laing, Madras Medical Service (ret), died on May 18th, aged 84 He was born on September 11th, 1845, the son of David Laing, Esq, of Edinburgh, and was educated at the university in that city, where he graduated as M B and C M in 1869, after taking the L R C P in 1866 Entering the I M S as an assistant surgeon on April 1st, 1870, he became Surgeon Lieutenant-Colonel after twenty years' service, and retired on September 9th, 1895

Major Charles James Owen Young, M C, R A M C, died at Kuala Lumpur, Federated Malay States, on July 30th He was the elder son of Colonel C A Young, C B, C M G and was educated at Trinity College, Dublin, where he graduated as M B, B Ch, and B A O in 1916 He entered the Army at once, on July 1st, 1916, as a lieutenant in the Special Reserve, R A M C, became temporary captain on December 1st 1918, captain on January 1st, 1920, and major on July 1st 1928 He served through the latter half of the war of 1914-18, was mentioned in dispatches in the *London Gazette* of December 30th, 1918, and was awarded the Military Cross

Obituary

SIR FRANCIS HENRY CHAMPNEYS, BT., M.D., F.R.C.P.

Consulting Physician-Accoucheur, St. Bartholomew's Hospital.

FRANCIS HENRY CHAMPNEYS, who died on the morning of July 30th, at his home, Littlemead, Nutley, Uckfield, Sussex, was born on March 25th, 1848, as the fourth son of the Very Rev. William Weldon Champneys, rector of St. Mary's, Whitechapel, and Dean of Lichfield, who father and grandfather had also been in Holy Orders. Francis's elder brother, Basil, a well-known architect, edited the *Memoirs and Correspondence of Coventry Patmore* (1900), a younger brother, Arthur Clark, who was a boy and later assistant master at Marlborough, was part author of a history of that public school (1893).

In 1860 Francis Champneys went to Winchester as a scholar, and was a pupil of S. S. Wesley, who was then organist both to the cathedral and the school (1849–65); this must have influenced his musical life for he had an organ in his house during the last quarter of the last century, directed a private choir which usually met in his London house, composed anthems and wrote articles in the *Dictionary of Musical Terms* (1876) compiled by Sir John Stainer and A. W. Barrett. In his *History of St. Bartholomew's Hospital* Norman Moore said that "as a learned and admirable musician he benefited the school of St. Bartholomew's by encouraging the practice of *music there*." Following the example of his father, who had been a Fellow of the college, Francis Champneys went up in October, 1866, to Brasenose, Oxford, and in 1868 rowed bow in the college four in the Stewards' Cup at Henley. He obtained a first class in natural science, together with Seymour J. Sharkey (1847–1929), in the final schools, and the B.A. degree in 1870. He entered the medical school of St. Bartholomew's Hospital in 1871, and while working in the dissecting room there made his first professional contribution—an account of "A communication between the external iliac and portal veins" in an "aged" woman of 48 years (*Journ. Anat. and Physiol.*, 1872, v, 427). The Radcliffe Travelling Fellowship for three years was awarded to him in 1872, the year before that honour was gained by Sharkey, whose career and life so closely corresponded with his. He thus had the opportunity of working at Vienna, Leipzig, and Dresden, and at the last of these medical centres held a post in the lying-in hospital, thus very probably determining his future line of work.

After fulfilling the obligations of the travelling fellowship to spend eighteen months of its tenure abroad, he returned to London, and in 1875 obtained the diploma M.R.C.S. and graduated B.M. Oxon., it was not however until 1878 that he proceeded D.M. At St. Bartholomew's he was appointed medical registrar in 1875 and in 1877 casualty physician at the same time as Robert Bridges, afterwards Poet Laureate. In 1876 he married Virginia, daughter of Sir John Warrender Dalrymple of North Berwick, and began the hard struggle in consulting practice which is easier to look back upon than to endure cheerfully, and which in his case led to such eminent success. In 1880 he was elected assistant obstetric physician to St. George's Hospital and on the retirement of Robert Barnes in 1885 was made obstetric physician, no appointment of a second obstetric physician was made during his term of office, so that he had entire charge of the department until 1[illegible]. In January 1891 he accepted the invitation to return to his old school St. Bartholomew's to take the place of J. Matthews Duncan (1826–1890), as physician accoucheur and lecturer on diseases of women and children, a post he held until his retirement in 1913 under the 65 years age limit when he was elected consulting physician-accoucheur and governor of the hospital. In this year he retired from practice and left his house in Upper Brook Street to live in the country.

He was a [illegible] pupil and follower of Matthew Duncan who had been appointed to the post in 1877, a time when the [illegible] had become [illegible] and Champneys [illegible] to be [illegible] lecture at 9 [illegible] went [illegible] Great St. George H[illegible] [illegible] [illegible] [

occupied the presidential chair of the Royal Medical and Chirurgical Society were Sir Charles Locock, first physician-accoucheur to Queen Victoria, in 1857, and in 1877 Charles West, who was honorary physician-accoucheur and lecturer on midwifery (1848–61) at St Bartholomew's Hospital, and also eminent as founder, in 1852, of the Great Ormond Street Hospital for Sick Children Now, after a shorter interval of seventeen years, Dr T W Eden follows in his footsteps As recently as July 15th last Champneys was elected an honorary Fellow of the society he had served so long and faithfully, but did not live to be admitted or to receive the diploma At the old Obstetrical Society of London, which became a Section of the Royal Society of Medicine, he filled many offices, and was president so long ago as 1895–96, when in his address he gave an account of the midwives question, in which he took a great and active interest for many years, playing a leading part in formulating the rules for the Central Midwives Board, and as its chairman since its institution becoming the authority on the subject, as is shown, among other ways, by his address in 1914 on the working of the Midwives Act (England), 1902 Many of his contributions are to be found in the Obstetrical Society's *Transactions*—for example, his paper on the mechanism of the third stage of labour (1888) In 1890 he delivered the Harveian Lectures on painful menstruation, which were published in the following year His deep interest in combating venereal disease was shown by his support of the British Social Hygiene Council, of which he was a vice-president At the British Medical Association's meeting at Oxford in 1904 he was president of the Section of Obstetrics and Gynaecology

Among his professional publications mention may be made of a volume in the New Sydenham Society's Selected Monographs—Landau's work on "Movable kidney in women," which he translated, annotated, and edited in 1884 He published in 1887 an account of experiments on artificial respiration in stillborn children, and later a study of the natural history of tubal gestation illustrated by a series of seventy-five original cases (1902), and a note on the history of the literature of the toxaemia of pregnancy (1908), the two last appearing in the *Journal of Obstetrics and Gynaecology of the British Empire*

In June, 1910, he was created a baronet of the United Kingdom, the same list containing the peerage conferred on Sir Balthazar Walter Foster, who had been Parliamentary Secretary of the Local Government Board His outstanding position in the medical profession was also shown by his election as president of the Section of Obstetrics and Gynaecology at the Seventeenth International Congress of Medicine, held in London in August, 1913 At the first meeting of the council of the College of Obstetricians and Gynaecologists, in September, 1929, he was appointed vice-patron of the college "in recognition of his services to obstetrics and gynaecology, and to the College during the process of formation" He was one of the original signatories of the college and a member of its first council, he regularly attended its meetings, and his judgement and sound common sense proved most valuable

Champneys advanced the branch of medicine he adorned rather by wise leading and tactful guidance than by initiating any great discovery, and he exerted an influence for reform and wholesome advance on sound scientific lines He had lived through the transitional period during which its followers, formerly physicians in name, became surgeons both in name and in deeds With a personal charm of manner and conversation, he had troops of friends, was a member of several social medical clubs, had wide interests outside his profession, and was a truly religious man His only surviving son, who succeeds to the title, Weldon Dalrymple-Champneys, late Grenadier Guards, was at Oriel College, Oxford, is a doctor of medicine, and a medical officer in the Ministry of Health

The funeral took place at Hampstead Cemetery on August 2nd, preceded by a requiem and the first part of the service at St Alban's, Holborn, with which he had long been associated A memorial service was held in the Church of St Bartholomew-the-Less, within the precincts of the hospital, at 9 15 a m on the same day

H D R

Sir D'Arcy Power writes

My earliest recollections of Dr Champneys go back to a time when he was canvassing for the appointment of obstetric physician to St George's Hospital, where my father had been ophthalmic surgeon and had many friends among the staff Champneys often stayed to dinner, and I recall him as a good-looking man, full of energy, talkative, and bubbling over with laughter He told us of Wagner's genius and of the relative beauties of his different operas, all of which he himself attended regularly, though seats were expensive, and money was not too abundant even for one who had been a Radcliffe Travelling Fellow at Oxford We learned also, incidentally, that it took just forty-nine minutes to walk from our house in Great Cumberland Place to Hampstead, where Miss Dalrymple, his future wife, was then living, and that he did the journey daily A few years later, when I attended the lectures of Dr Matthews Duncan—that great teacher of ethics and midwifery—Champneys was always present, notebook in hand, although he was obstetric physician at St George's, and Dr Matthews Duncan lectured "on every lawful day—Saturdays included—at 9 a m" Later still came the distressing incident when Dr Clement Godson was superseded, Dr Champneys was then elected physician-accoucheur to St Bartholomew's Hospital in place of his great master From that time his position was assured, he went from honour to honour, happy in his circumstances until those last sad years when, bereft of a son in the war and of a beloved wife, he fell into the sadness of old age Of him it was true, as Virgil sings, that—

> "Optima quaeque dies miseris mortalibus aevi
> Prima fugit, subeunt morbi tristisque senectus"

Dr David John Browne, who died at his residence in Londonderry on June 19th at the age of 84, received his medical education in Dublin, where he obtained the diplomas L M in 1868 L R C S I in 1869, and M R C P I in 1880 The whole of his medical career was spent in Londonderry, where he built up a large practice He held several public appointments, being consulting medical officer of health to the Londonderry Union, physician to Foyle College, and medical referee to various insurance companies He was for some time a member of the Derry Corporation, and until his death he was a director of the City of Derry Building Society, of which he had been president for the last fourteen years He was a member of the British Medical Association A colleague writes Of a genial and kindly nature, Dr Browne was a practitioner of the old school He was highly esteemed by everyone with whom he came into contact His bright, cheery manner, coupled with a fine sense of humour inspired many of his patients in the critical stages of their illness, and he was regarded as a family friend as well as medical adviser Some years ago, when he retired from the post of medical officer of the Derry Workhouse and Waterside Infirmary, which he had held for over forty years, the chairman and members of the board of guardians paid the highest tribute to the very efficient manner in which he had discharged his duties

---

Dr Charles Berkeley Gervis, who died on June 30th, was born at Hampstead in 1875, he was the fourth son of the late Dr F H Gervis, who practised for many years in Fellows Road Charles Gervis was educated at St Paul's School and University College Hospital, and studied also in Brussels and Vienna He obtained the diplomas of M R C S Eng, L R C P Lond in 1897, and graduated M D Brux in 1898 After serving as assistant medical officer at Colney Hatch Asylum he went to Seaford in 1898 he subsequently held the appointments of medical officer to the Post Office and public vaccinator of the Seaford District of the Eastbourne Union He took great interest in local affairs, being a member of the Seaford Urban District Council for sixteen years and chairman of that body for three years He was also chairman of the Seaford Nursing Association, the committee of the Sussex County Hospital, and the Boy Scouts local association He founded the Seaford Masonic Lodge, and was for many

years honorary secretary of the Union Club. During the war he served with the R.A.M.C. in France and South Africa. Dr. Corvis was a member of the Brighton Division of the British Medical Association. He contributed a paper on eclampsia to the *British Medical Journal* in 1913.

Dr. DAVID HART SCOTT, who died on June 28th at the age of 72, received his medical education at the University of Edinburgh and obtained the diplomas L.R.C.P., L.R.C.S. and L.M. Ed. and L.R.F.P.S. Glas. in 1884. After holding the post of assistant house surgeon at the Dumfries and Galloway Royal Infirmary he engaged in general practice in Manchester and afterwards at Paddock Wood, Kent, acting as district medical officer for the Capel District of the Tunbridge Union. He later practised at Sampford Peverell, Devon, and subsequently at Bolton le Sands, finally settling down at Pirton, Drove, near Wisbech, in 1919. He took an active interest in the affairs of the Isle of Ely Division of the British Medical Association, and became a member of the Executive Committee of that Division in 1919. He was elected vice-chairman of the Division in 1928, and would have held the post of chairman the following year but for his illness, which ultimately proved fatal. In addition to his interest in the affairs of the Division he also took an active part in those of the Isle of Ely Panel and Local Medical Committees, on both of which committees he served from 1919 onward. A colleague writes: Dr. Hart Scott had the attributes in no small degree which go to the make up of an ideal type of man—the combination of the Christian gentleman and the doctor. He never sought popularity, but with such a character he was destined not to escape it. He was held in high esteem among his colleagues, and was truly beloved by his patients, on whose behalf he laboured unsparingly. He will always be remembered for his kindly disposition, his sincere desire to relieve suffering, and his warm, human sympathy.

Medico-Legal

MEDICAL FEES AT INQUESTS

CLAIM AGAINST A CORONER

At Redhill County Court, on July 16th, His Honour Judge Hill Kelly gave a reserved judgement in an action which had been brought by the Medical Defence Union, acting on behalf of Dr. David Low Greig of Caterham, against the coroner for East Surrey, Mr. F. J. Nightingale. Dr. Greig claimed £22 1s. for examining seven bodies and giving evidence on two occasions as to cause of death in the case of the victims of the Croydon air disaster of November 1929. The Medical Defence Union contended that the doctor was entitled to a fee in the case of each body examined, whereas it was contended by the coroner that as the cause of all these deaths was dealt with by one inquiry Dr. Greig was only entitled to two fees of 1½ guineas as if one inquest had been held on one body on two occasions.

At the hearing, which took place on June 20th, Mr. H. C. Dickens (instructed by Messrs. Hempson, solicitors) represented Dr. Greig and the Medical Defence Union, and Mr. Milner Holland represented the coroner and the Surrey County Council, his employing authority.

Mr. Dickens explained that this was a friendly dispute as a result of which it was hoped to get an interpretation of Section 23 of the Coroners Amendment Act, 1926. The section reads as follows:

> The fees payable to a legally qualified medical practitioner who has made any post mortem examination by the direction or at the request of a coroner or who has attended an inquest in obedience to a summons of a coroner under the Coroners Act, 1887, shall (save as in this Act otherwise expressly provided) be as follows—that is to say:
>
> (*a*) For attending to give evidence at any inquest whereat no post-mortem examination has been made by the practitioner, 1½ guineas for each day of which he is required to attend; and
>
> (*b*) for making a post mortem examination of the body of the deceased and reporting the result thereof to the coroner without attending to give evidence at an inquest, 2 guineas; and
>
> (*c*) for making a post mortem examination of the body of the deceased (including the making of a report, if any, of the result thereof to the coroner) and for attending to give evidence at an inquest on the body, 3 guineas for the first day and 1½ guineas for each subsequent day on which the practitioner is required to attend:
>
> Provided that no fee or remuneration shall be paid to a medical practitioner for the purpose of a post mortem examination instituted without the previous direction or request of the coroner.

On November 7th (Mr. Dickens continued) Dr. Greig made an examination of the bodies of seven persons who were the victims of an air disaster, and on the following day attended an inquiry into the causes of death. The inquiry was adjourned, and Dr. Greig attended again at the resumed hearing. His submission was that he was entitled to seven 1½ guinea fees in respect to his services on the first day, and a similar amount in respect to his services on the second day.

The coroner, in evidence, said that he issued only one coroner's warrant, empanelled only one jury, and returned one verdict. He agreed that he viewed seven bodies, that there were seven inquisitions, seven death certificates, and seven burial orders, also that there was a possibility that the cause of death might have been different in each case, though in fact it was not.

Mr. Holland for the coroner submitted that there was no obligation on the part of a doctor to examine the bodies when requested to do so by the coroner's officer. The only thing which could be enforced was attendance at the inquest. When the judge whether he was putting this forward for the defence on behalf of such a responsible body as the Surrey County Council, he said that that in his submission was the law, to which the judge replied: 'How is the coroner to get a medical man to give evidence as to the cause of death if he has no power?' Mr. Dickens also pointed out that if the coroner had no power over a medical man the medical man could go into the witness box at the inquest and say that he could give no evidence as he had not seen the body. At the same time, he would be entitled to his fee of 1½ guineas for attendance.

Judgment for the Doctor

In giving judgement His Honour said that Section 23 of *the Coroners Amendment Act indicated the manner in which* a practitioner was to be remunerated in three different sets of circumstances—namely (*a*), (*b*) and (*c*). It was the first one which fell to be considered in this case—attendance to give evidence without having made a post mortem examination—but in order to construe the section it was proper to have regard to the whole of it. Clause (*a*) might be ambiguous when read alone; it seemed clear that Clause (*b*) gave to the practitioner a right to a fee of 2 guineas for each post mortem examination made by him at the coroner's direction, while Clause (*c*) provided that *the practitioner should be entitled* to be paid 3 guineas for making a post mortem examination of the body and for attending to give evidence at the inquest. If the defendant's contention as to the construction of the section was correct, how was the remuneration of the practitioner to be ascertained in the case coming under Clause (*c*)? Suppose an inquiry into the deaths of two persons killed at the same time and by the same cause, and that the practitioner had by the coroner's direction made post mortem examinations of the two bodies and had attended the inquest: the evidence with regard to both bodies [illegible] was he to be remunerated. The [illegible] ended the operation of Clauses (*a*) and (*b*) and [illegible] Clause (*c*) which enabled the fee of 3 guineas to be split up. On the other hand, if the application was correct, there was no difficulty: the practitioner in that case was entitled to be paid 3 guineas in respect of each post mortem examination he had made where he had also attended to give evidence of the cause of death. Therefore it would follow from the words in Clause (*c*) attending to give evidence at an inquest on the body that an inquiry touching the death of one person and no more was intended, and if the word was used in that sense in Clause (*c*) it followed that it was used in the same sense in Clause (*a*). That the judge thought was the true view of the matter. Although it was [illegible] practice for coroners to hold a single inquiry into the deaths of two or more persons there were really in the law as many inquiries as there were dead bodies touching which [illegible] was held. The language of the *Coroners Act, 1887*, and the *Coroners Amendment Act, 1926*, throughout [illegible] inquiry touching the death of a single person, and there the word used was [illegible] of the Act of *1926* and there the judge [illegible] in the plural whereby the judge [illegible] recognized that a separate inquest [illegible].

The result of this interpretation [illegible] Dr. Greig was entitled to [illegible] application Dr. Greig claimed [illegible] the amount he claimed [illegible] a practitioner should be entitled to be paid a large sum in respect of [illegible] attendances occupying a [illegible] whether [illegible] the case was unusual when a coroner inquired into the deaths of seven persons killed at the same time and a strange result in an unusual case ought not to affect the interpretation of the Act.

The judge added, "Since the rate of remuneration of the medical practitioner is governed by the words of the Act of Parliament no question can arise as to its reasonableness, but the plaintiff naturally referred in his evidence to the fact that, at the defendant's request, he attended on the day before the inquiry at the Caterham mortuary and examined the six bodies lying there [the seventh person died at the house of the plaintiff], and since if he had not attended at the mortuary and made that examination he could have given no evidence for the guidance of the coroner and the jury, it was with considerable surprise that I heard counsel for the defendant repeatedly urging that the plaintiff was under no obligation to comply with the request and could have wholly disregarded it without any breach of duty."

Judgement was given for the plaintiff, but His Honour agreed to a stay of execution for twenty one days

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT]

ON August 1st before Parliament was prorogued till October 28th, the Royal Assent was given to the Workmen's Compensation (Silicosis and Asbestosis) Act, the Road Traffic Act, the Criminal Appeal (Northern Ireland) Act, the Education (Scotland) Act, the Housing Act, the Housing (Scotland) Act, and to other Acts. The King's Speech proroguing Parliament recalled that at an earlier date the Royal Assent had been given to the Mental Treatment Act.

On the same day Mr Snowden read to the House of Commons a statement setting out the Government's agricultural policy. Dr Fremantle pointed out that this contained no reference to a subject of great importance—namely, the training of veterinary surgeons.

National Health Insurance

Mr GREENWOOD informed Sir N. Grattan-Doyle on July 31st that he had seen the report of the Council of the British Medical Association recommending the extension of the benefits of national health insurance to dependants of all persons insured thereunder. He was not then able to make a statement concerning any action.

Replying to Dr Vernon Davies Mr GREENWOOD said he knew Section 4 of the National Health Insurance Act, 1928, precluding Insurance Committees from making grants unless the Minister was satisfied that they were [illegible] character, would abolish next December the [illegible] service of the Lancashire Insurance Committee. Dr DAVIES stated that since 1926 this service had provided out of local funds a free laboratory diagnostic service for 800,000 insured persons in Lancashire at a cost of less than one farthing per head. Mr GREENWOOD remarked that alternative means of securing services of this character had been suggested to representatives of the committee, but he could not undertake to propose an amendment of the law deleting the word "eleemosynary" from Section 4 of the Act of 1928.

Replying to Mr Daggar Mr GREENWOOD gave the approximate number of weeks for which sickness and disablement benefits were paid under the National Health Insurance Acts:

Years	Million weeks	Years	Million weeks
1921	19	1926	28¼
1922	19¼	1927	30¼
1923	20¼	1928	26¾
1924	23¼	1929	29¼
1925	25		

In reply to Mr Gould, on the same day, Mr GREENWOOD said he had received a report from the Somerset Health Insurance Committee in which it was stated that certain chemists had been dispensing in a very lax way under the National Health Insurance Act, and that in one case a deficiency of 69 per cent of the drugs as prescribed by the medical practitioner was dispensed to the patient. Any failure to comply with the terms of service applicable to insurance chemists would be dealt with in accordance with the Medical Benefit Regulations. Asked by Mr GOULD whether he would not take action in order to dispel the bad impression the report had left on the minds of patients in regard to the quality of dispensing Mr GREENWOOD said that there was no delay on his part. A definite procedure had to be followed under the regulations in regard to intervention.

Mental Treatment

Mr GREENWOOD stated in reply to Mr Richardson on July 30 that in the course of considering the recommendations of the Royal Commission on Lunacy notes were prepared on the clauses that would be required to effect an assimilation of the procedure for the certification of rate-aided and private mental patients. No steps had been taken towards drafting a bill, as it was impracticable at present to undertake further lunacy legislation. When asked to state his attitude towards the recommendation of the Standing Committee on the Mental Treatment Bill to give separate accommodation to voluntary boarders, he reminded Mr Richardson that the Mental Treatment Act had only received the Royal Assent on July 10th and did not come into operation until January 1931. The Board of Control had already conferred with local authorities in regard to some of the more important provisions of the Act. Until local authorities had an opportunity of considering and determining the steps to be taken in their areas when the Act came into operation it was impossible to say how many hospitals which had hitherto been Poor Law infirmaries would be utilized for this purpose or how many hospitals had started out-patient clinics for mental cases.

On August 1st Mr GREENWOOD announced that he had given provisional approval to a proposal made jointly by the East Riding County Council and York City Council to buy Brandesburton Hall and 98 acres of land for "mental deficiency purposes." The estate had been inspected by the Board of Control, which was satisfied that it was suitable. His own inquiries did not support the allegation that the site was unsuitable and too low.

Physical Condition of Army Recruits

In the House of Commons, on July 30th, the Army Estimates again came under discussion, and a statement was made by Mr SHAW. He said that the Army needed about 30,000 recruits a year, of whom 17,000 were required for the infantry. Something like 61 per cent of those who offered themselves for the Army failed to reach the very moderate standard of physical efficiency which was necessary. During the nine months of the present recruiting year 19,213 recruits were accepted. The physical condition of those now offering themselves for service was probably due to the war. In addition, the diminution of births during the war years limited the number of men of military age. In 1928, 64 men out of every 100 were rejected, and in 1929, 61. Nearly all the rejections were on account of physical defects. The height required for the infantry of the line was now 5 ft. 2 in. To him these figures were dreadful. The medical side of the Army was understaffed. From information given him by some of the distinguished men in the medical profession, the reason was that the terms on this side of the service were *not good enough*.

Sir LAMING WORTHINGTON EVANS said that in past years 65 or 66 per cent. of Army recruits had been rejected. He did not see how war deterioration could yet affect recruiting. War children would at most be only 16 years old.

Mr SHAW said he had referred to the children who were 3 or 4 years old when the war broke out.

Dr VERNON DAVIES said the recruiting statistics showed there were in this country a very large number of young men who could not be described as physically fit. The improvement on young men after admission to the Army should be taken into account. Mr Shaw had recently stated that there was a present shortage of 140 medical officers in the Army. Mr Shaw had put his finger on the cause, which was money. The medical man was worthy of his hire, and more and more of them were attracted each year into the public services—the health services, tuberculosis services, venereal disease services, and all the others, which offered great inducements. The best men took these appointments and the Army suffered. If the Secretary of War offered sufficiently good terms he could get them into the Army. There was another method. Would it not be possible to arrange that any medical man who had been in one of the Defence Services should have a preferential claim to any Government medical service, and later on, to those under municipalities? The same trouble was found in the Navy and the Air Force, but if the three departments would persuade the Government to adopt this preferential system the difficulty would be overcome.

The House then agreed to the Army Estimates.

A previous discussion on the Army Estimates and on the shortage of medical officers occupied the House of Commons on March 24th, and was reported in the *British Medical Journal* of April 12th.

Medicine Stamp Duty.—In an answer to Mr Leif Jones, on August 1st Mr SNOWDEN said the net amount of Medicine Stamp Duty received in the year ended March 31st, 1930, was approximately £1,234,200. There was a statutory exemption from the duty in favour of "Known, admitted and approved" remedies—when sold by duly qualified doctors, chemists, or druggists—in which no proprietary right was claimed. Claims for such exemption were admitted provided that a definite and complete statement of the actual ingredients (that is, the full formula with proportions) and a statement that no proprietary rights were claimed in the preparation of the medicine were printed in a legible and conspicuous manner on all labels, cartons, etc. Following the decision of the courts in the case of Farmer *v.* Glyn Jones in 1903, exemption had not been refused on the ground that known, admitted, and approved remedies had been recommended for the prevention or cure of illness. The cost of this exemption could not be stated.

Smuggling of Drugs.—Mr CLYNES, in reply to Mr Mander on July 31st, stated that there had been a number of attempts to smuggle drugs into Egypt on boats of the Khedivial line, and on those of other lines sailing between Egypt and European ports. The Central Narcotics Intelligence Bureau in Cairo had called the attention of the company to these cases, and the company had instructed their agents to co-operate in every possible way with the Bureau to prevent use being made of their ships for such a purpose.

Tuberculosis.—Mr ALEXANDER informed Dr Vernon Davies, on July 30th, that during the previous six months 70 per cent. of those invalided from the Navy for tuberculosis had been granted attributable pensions. This compared with 68 per cent of those invalided for this reason during 1929. On the same day Dr Davis was told by Mr SHAW that the number of such pensions granted to those who had been invalided from the Army during 1929 on this account was about 2 per cent less than the number of the previous year.

Housing.—During the period July 1st 1928 to June 30th, 1929 51,282 houses were built in England and Wales under the Housing Act, 1924; in the following year the number for the same period was 54,159.

Vagrancy—Mr GREENWOOD stated last week that the report of the Commission on Vagrancy would shortly be available He proposes to address a circular letter regarding it to local authorities

London Refuse—In reply to Dr Fremantle on July 31st Mr GREENWOOD said the report of the Departmental Committee on the Disposal of London Refuse was being considered by the Standing Joint Committee of the Metropolitan Borough Councils It would not be practicable for the committee to furnish its view during the parliamentary recess

Anthracosis in Miners—Mr PARKINSON in reply to Mr Jenkins on July 30th said the investigation of anthracosis in miners was within the scope and under the close attention of the Committee on Industrial Pulmonary Disease recently set up by the Medical Research Council The results of the investigations would be published in due course

Infant Mortality in Malta—Dr SMITH replying to the Duchess of Atholl on July 28th said that during 1923 there were 1 653 deaths or 250 81 per 1 000 births of children under 1 year of age in Malta In 1927 there were 2 250 deaths or 301 32 per 1 000 births and in 1928 1 963 deaths or 267 91 per 1 000 birth

Medical News.

VISITS to the Tower of London will be arranged on August 13th 20th and September 3rd in aid of King Edward's Hospital Fund for London the guide being Mr Walter Bell, the well known London historian Applications for tickets (price 10s for each visit) should be made to the secretary of the Fund 7, Walbrook, E C 4

THE winter session of lectures at the Central London Throat, Nose, and Ear Hospital Gray's Inn Road W C 1, will commence on Friday, September 5th at 4 p m The official opening lecture of the session will be given on October 10th at 4 p m by Dr Dan Mckenzie, on the limitations of surgery in oto laryngology

THE Fellowship of Medicine announces that there are still three weeks remaining of the special course in urology consisting of clinical and cystoscopic demonstrations on male and female patients at All Saints Hospital Vauxhall Bridge Road, S W 1 proportionate fees are payable From August 11th to 16th an all day course will be held at the Brompton Hospital A course taking up the whole of the day will be held at the Queen's Hospital for Children from September 1st to 13th, the instruction will consist of the showing of cases rather than set demonstrations or lectures There will be a revision course at the Westminster Hospital from September 15th to 27th when the various departments of the hospital will be utilized for providing instruction in all branches of medicine and surgery Post graduates are invited to apply for particulars of the work arranged for the winter months and also for the 1931 list of special courses full information is obtainable from the secretary of the Fellowship, 1, Wimpole Street, W 1

THE following international post graduate courses have been arranged in Berlin (1) Practical laboratory course September 29th to October 4th fee 40 marks (2) Internal medicine, with special reference to its clinical aspects fee 75 marks, (3) paediatrics September 29th to October 11th, fee 100 marks (4) ophthalmology October 1st to 11th, fee 80 marks and (5) occupational diseases, October 27th to November 4th, fee 60 marks

THE autumn session of training courses for examinations for sanitary inspectors, meat and food inspectors smoke inspectors associateship (general hygiene and sanitation), associateship (food hygiene) and sanitary science will commence at the Royal Sanitary Institute on Monday, September 29th Syllabuses of the lectures and of the examinations are obtainable from the secretary, 90, Buckingham Palace Road, London, S W 1

THE Medical Society of Individual Psychology, which has met hitherto at 55, Gower Street London will in future meet at the rooms of the Medical Society of London, Chandos Street, W 1 The primary object of the society is to bring together those interested in the medical aspects of individual psychology and to give instruction as regards its theory and practice Meetings are held for the reading of papers and the holding of discussions A course of systematic lectures is proposed for the early part of next year The first meeting of the society during the coming session will be held on Thursday October 9th when the chairman Dr O H Wood cock will give an address on the development of individual psychology in the twentieth century Further information as regards membership of the society and other meetings may be obtained from the secretary Dr T E Lawson 35a Welbeck Street W 1

A MEETING of the National Radium Trust was held on July 29th under the chairmanship of Lord Parmoor when considerable was given to the report to be submitted in the autumn to the Treasury for presentation to Parliament

AT the meeting of the council of the Metropolitan Hospital Sunday Fund held at the Mansion House on July 30th it was announced that the sum of £73,000 had been subscribed this year, being £5 000 less than the figure for the previous year It was stated that the money had been distributed among 237 hospitals, institutions, dispensaries and nursing associations 7½ per cent had been appropriated for the purchase of surgical appliances, and 2½ per cent for district nursing associations

THE Medical Research Council has appointed Major A G Church M P, Dr F E Fremantle, M P and Sir John H Parsons F R S, to be members of its Industrial Health Research Board

IN view of the passing of the Road Traffic Act 1930 the Automobile Association has prepared a booklet giving a digest of the main features of the law which affect the owners of motor cars and motor cycles The booklet is obtainable by post-card application to the secretary of the Automobile Association Fanum House New Coventry Street W 1

MESSRS BUTTERWORTH AND CO the publishers of Dr J D Polleston's *Infectious Diseases and Other Fevers in Infancy and Childhood* have sent us a copy of a slip, which is being inserted in all copies of the book sold to the effect that certain passages which were noted in the *Journal*, January 25th p 156) had inadvertently been taken without acknowledgement from the first edition of Dr J D Polleston's book on *Acute Infectious Diseases*

A SOUVENIR booklet has been issued by the Church of England Zenana Missionary Society describing its religious, educational and medical work in India and China since it was founded as a separate organization fifty years ago In that period the society has organized twenty three hospitals and twenty seven dispensaries to alleviate suffering among women and children and to provide training for native nurses and midwives It also maintains several schools for the deaf and blind in both countries Copies of the booklet which contains a number of striking tributes, are obtainable at the offices of the society 19 to 21 Southampton St, W 1, price 1s

ST Bartholomew's Hospital old students annual dinner will be held on Wednesday, October 1st at 7 30 p m in the great hall of the hospital with Mr L B Rawling in the chair The honorary secretary is Sir Charles Gordon Watson, 82, Harley Street, W 1

IN order to make the results of the researches carried out at the National Physical Laboratory more readily available to the public the annual report of the Laboratory for 1929 (reviewed in the *British Medical Journal* of June 21st) has been published in a number of separate pamphlets as well as in volume form These pamphlets which include the reports of the physics electricity metrology, engineering aerodynamics, and metallurgy departments are obtainable at H M Stationery Office

THE fourth Congress of the World League for Sexual Reform will be held in Vienna from September 13th to 20th when papers will be read on housing and sexual reform birth control, the rights of the child and the history of sexual morality

As a memorial to Richard Cadbury and George Cadbury, who created Bournville fifty years ago the firm of Cadbury Bros, Ltd have presented Frankley Beeches near Birmingham, to the National Trust to be preserved free from buildings

HARROW HOSPITAL has received an offer from the Kodak Company to build and equip an x ray room at a cost not exceeding £1 000

DR ROBERT S BRIDGES the Poet Laureate from 1913 to 1930 who died on April 21st aged 85 years has left estate of the gross value of £5 928 with net personality £5 771

THE Hungarian Ministry of Social Welfare has offered a prize of 2 000 Swiss francs for the best original work on the causes of trachoma The work which may be written in English, German, French Italian or Hungarian should be sent to the Ophthalmological Clinic of the Hungarian University Budapest, before June 30th 1931

PROFESSOR ALBERT DÖDERLEIN director of the gynaecological clinic at Munich has been elected honorary president of the Munich *Gynaecological Society* on the occasion of his seventieth birthday

THE following appointments have recently been made in foreign faculties of medicine Dr Cunéo professor of topographical anatomy and operative surgery and director of medico-chirurgical anatomy in the Paris Faculty Dr I Tesson professor of clinical surgery in the Paris Faculty Dr professor of surgical pathology in the medical school of Angers in succession to the late Professor Brin and Dr Schreus professor of dermatology at Düsseldorf

GEHEIMRAT DR PAUL KRAUSE director of the medical clinic at Münster has been elected Rector of the Münster University for 1930-31 and the well known dermatologist Professor Ladislaus Nekam has been elected Rector of Budapest University

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W C 1***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W C 1, on receipt of proofs

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines)

The ***TELEGRAPHIC ADDRESSES*** are

EDITOR OF THE *BRITISH MEDICAL JOURNAL, Aitiology Westcent, London*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc) *Articulate Westcent, London*

MEDICAL SECRETARY, Mediocrea Westcent London

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams *Bacillus, Dublin*, telephone 62550 Dublin), and of the Scottish Office 7, Drumsheugh Gardens Edinburgh (telegrams *Associate, Edinburgh*, telephone 24361 Edinburgh)

QUERIES AND ANSWERS

SOUR MILK

'E W D' asks for advice about the conducting of the sour milk treatment in the case of persons unable to afford the expense and time involved in daily use of the various commercial preparations on the market He believes that in the Balkans, whence the treatment came, the souring process is kept up by simply transferring a small portion from milk already sour to a fresh bowl, and that there are people who adopt this method in Britain He would be glad to have particulars how this is done, and of the best preparation with which to start the process

UNUSUAL REACTIONS TO ULTRA VIOLET RAYS

DR P CLENNELL FENWICK (Christchurch New Zealand) writes Has anyone using the ultra violet rays had experience of unusual reactions following the use of this ray? A dark haired woman, aged 38, with five ulcers on the legs, was given local treatment with the ultra violet rays and also the usual bath over the whole body, the face being protected The ulcers began to heal well, but the skin over the body reacted quickly, and after the seventh bath treatment was discontinued for several days The whole body showed very marked dermatitis, with a number of crusting areas on the breasts, moreover the face which had not been subjected to the rays, peeled as if the patient had been badly sunburned The reaction was so violent that I was much concerned The skin quickly improved and the crusted areas healed well, but I do not understand why the face, which was never exposed to the rays, should show so marked a reaction

TREATMENT OF OBESITY

'A H' writes I know two medical men who speak highly of a cure of obesity by high rectal enemata and purely vegetable diet I have not been able to find any literature on the subject Is there any article or book available?

BROMIDROSIS

A V C, replying to the inquiry of 'R B C' in the *Journal* of July 12th (p 86) with reference to profuse and offensive perspiration, writes If the boy will use a nail brush and rub soap into the soles of the feet for a few days and afterwards soap the feet daily, especially the heels and the ball of the foot, nothing in the way of chemicals is necessary These boys are not taught to soap the soles of the feet when bathing or washing the feet Of course, well ventilated shoes are also desirable, such as canvas shoes in hot weather

DIET IN RHEUMATISM

T L' writes In reply to Dr Grant's inquiry in the *Journal* of July 19th (p 128) I should like to suggest a trial of the following diet for rheumatism All drinks should be unsweetened additional drinks—plain water, or water into which a little lemon juice has been squeezed—should be taken between meals Cocoa, tea and coffee are very beneficial without milk or sugar though a little milk can be added if necessary Grape fruit or lemon juice unsweetened, can be taken before breakfast If meat cannot be left out of the diet its quantity must be definitely reduced Sweet puddings of the starchy variety and stewed sweetened fruit are definitely injurious, these should be replaced by fresh fruits and nuts Potatoes are best baked and served with butter Salads can be freely indulged in The evening meal should be chiefly protein, starchy foods being replaced by fats as much as possible Fish, eggs, butter and cheese at night are better than pastries, etc Germ bread or ryevita biscuits will supply any deficiency which may be felt in the reducing of the bulk of the diet

LETTERS NOTES, ETC

IODINE IN THE PREVENTION OF MISCARRIAGE

DR J WINIFRED WARD (Chanda, India) writes In view of the remarks of Professor Beckwith Whitehouse in the *Journal* of December 14th, 1929 (p 1095), as to the value of iodine in pregnancy and of the cases of habitual miscarriage successfully treated by iodide and iron recorded by J Novak (see *Epitome*, June 5th, 1926, para 576), the following two cases may be of interest Both were referred to me from the local infant welfare centre and I have sent an account of them to the Central Provinces and Berar Red Cross Infant Welfare Committee The first patient was a healthy low caste Indian woman with a history of two normal pregnancies, *followed by five* pregnancies in which foetal movements stopped at the beginning of the ninth month and stillbirths took place She came for treatment in the *seventh month as she thought* foetal movements had ceased She received syrup ferri iodidi, and gave birth to a full time living male infant In the second instance *a high caste Indian woman was brought by her husband* in the seventh month of pregnancy, as she thought the foetal movements had much diminished and felt a sensation of weight in the lower abdomen She had had two stillbirths at the seventh month, following which her Wassermann reaction and that of her husband were tested and found to be negative The husband stated "The pathologist gave my wife some injections afterwards to make sure" She was treated by syrup of ferrous iodide and, since she stated that this made her vomit by powders of *sodium bicarbonate and magnesium carbonate* She gave birth to a healthy full time male infant

"UKUSIZA ABA LIMELE"

IN the Witwatersrand gold mines the native appears to have become deeply interested in first aid so that there are now over 22 000 natives possessed of first-aid certificates and badges DR H T H BUTT, senior medical officer of the Randfontein Estates Gold Mining Company, finding theoretical tuition unnecessary for the uneducated Bantu, has hit upon the plan of photographing natives in the process of applying splints and bandages, in resuscitating the apparently dead, and in carrying patients or placing them on stretchers The photographs have been collected in a little work entitled *Ukusiza Aba Limele*, the name of each injury is given in Zulu, Xosa Sesuto, and English and an occasional slogan in the same four languages is thrown in for the purpose, presumably, of encouraging any Bantu who can read to join the movement The booklet is published by the Rand Mutual Assurance Company, It has the blessing of the South African Red Cross Society and Dr Butt thinks that it may be of interest to Europeans This should be so, if only for the photograph natives seriously enjoying the processes of where did Dr Butt find the horrible word at is commonly called an appendix? His booklet is published by the Prevention of Accidents Committee of the Rand Mutual Assurance Co, Ltd

RETENTION OF URINE FROM LARGE VAGINAL CLOT

DR C J HILL AITKEN (Kilnhurst, near Rotherham) writes A multipara had post-partum haemorrhage I made her lie flat on her back and kept her so The oozing which continued I disregarded, as from her *oedematous condition* I judged she was albuminuric and the bleeding salutary The uterus was in good position and of a size and of a consistency normal to the puerperium *Thirty six hours later* I was called, as the patient could not pass urine and was in great pain The catheter withdrew about a pint and a half of urine Thereafter the bowels, which had been locked up despite a large dose of black draught acted freely, and a clot, which the friends took to be the after birth, came away Later the patient again passed water naturally Shears in his *Obstetrics*, warns his readers about the danger of retention of lochia if a patient too long lies on her back In this case the oozing blood accumulated (presumably—I did not examine per vaginam) and formed a massive clot in the upper vagina, hence the retention of urine

CINEMATOGRAPH FILMS AND CUSTOMS EXAMINATION

MESSRS KODAK who have *arranged to illustrate certain of the* papers to be read at the forthcoming meeting of the British Medical Association in Winnipeg write When cinematograph film subjects *cinematograph apparatus* or photographic apparatus which is dutiable in this country are taken abroad for temporary use, and will ultimately be brought back to Great Britain by the owner, it is advisable to submit such material to an examination by a Customs officer who in most cases will issue a form stating that the dutiable articles are to be re admitted free of duty *at a specified port of entry within a stated* period Sufficient time should be allowed for the necessary formalities to be complied with before embarking

VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges and of vacant resident and other appointments at hospitals will be found at pages 35 36, 38 39 42, 43 and 44 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 40 and 41

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page *104*

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine

120 Psittacosis in France

P PAGNIEZ and V PLICHET (*Bull et Mém Soc Méd des Hôp de Paris* April 28th, 1930 p 688) state that psittacosis appeared later in France than elsewhere in Europe They believe that one of the first cases occurred during the latter half of January 1930, in a man, aged 52, who suffered from persistent fever (103° F), digestive disturbances, and severe insomnia The abdominal and thoracic viscera were apparently normal and there was no headache nor exhaustion but the patient complained greatly of insomnia A blood culture was negative Eight days later signs of consolidation appeared at the right base with apricot coloured sputum and slight dyspnœa Insomnia was continuous The pneumonic signs persisted for a week, expectoration then became less and the temperature fell by lysis Bacteriological examination showed many pneumococci but Nocard's bacillus was not found The patient who kept a number of parrots had been bitten on the hand by one of the birds fifteen days prior to the onset of illness this caused an ecchymosis Another case occurred in the patient's family A HESSLER and P DECOURT (*ibid* p 689) who describe another very mild case of psittacosis remark that this disease had not been observed in France for twenty years but a number of cases have occurred in Paris since December 1929 A man aged 37 who was employed by a dealer in parrots had repeated rigors with a temperature of over 103° F and slight headache these symptoms came on a few hours after he had fed and caressed a sick parrot which died shortly afterwards For a week the patient's condition remained unchanged cough then developed associated with a coated tongue anorexia, and constipation A few days later physical signs of consolidation appeared at the left base but there was no evidence of enteric fever On the ninth and tenth days of the illness several attacks of epistaxis occurred Blood films showed moderate leucocytosis On the fourteenth day the general condition of the patient suddenly improved although the cough and physical signs persisted The spleen was palpable and the temperature oscillated for several days The patient recovered completely at the end of three weeks Bacteriological tests were negative

121 The Significance of Essential Hypertension in Young Male Adults

P S PALMER (*Journ Amer Med Assoc* March 8th 1930, p 634) tabulates the results of examination of 3 593 men whose average age was under 20 Examinations were made between 1914 and 1918, and a large number of cases have been followed for a ten year period Of the total number slightly more than 10 per cent had a systolic blood pressure of 140 mm Hg and upwards while 2 25 per cent had one of 150 mm and upwards, without urinary or other abnormalities the systolic pressure in all these cases was more than 10 per cent above the average taking age, height and weight into consideration Half of these individuals had diastolic pressures more than 10 per cent above the calculated normal, in a normal control group only one quarter showed a similar diastolic abnormality It was noted that of the "normal" controls 2 13 per cent were of a "neurotic type whereas of those with systolic pressures of 140–150 mm 8 3 per cent were of this type and of those with systolic pressures of 150 and over 16 per cent No correlation was found with a previous history of infectious disease this contrasts with Barach's finding of a correlation with previous typhoid fever and diphtheria There was a slight increase of the proportion of overweight persons in the hypertensive group, with an increase in the proportion of "underweight" persons also among those with systolic pressures over 150 mm Of 115 persons followed up for ten years, 66 were normal controls and 49 hypertensives of the former 4 5 per cent had systolic pressures of 140 mm or over and one patient of 150 mm , of the latter 12 2 per cent had systolic pressures of 140–150 and 10 2 per cent of 150 or over the highest being 180 The main conclusion drawn from the research is that if hypertension is present at the age of 20, it is more likely to persist than it is to arise *de novo* in a normal subject Vasomotor symptoms such as palpitations and flushing were observed during the ten year period in a quarter of the hypertensive subjects as compared with only one seventh of the controls In both groups the incidence of familial cardiovascular disease was approximately the same

122 Recovery from Amyloid Disease

H WALDENSTRÖM (*Nord Med Tidsskrift* June 7th 1930 p 953) remarks that pathologists and clinicians have hitherto regarded the deposit of amyloid matter in the tissues of man as an irreversible process During the past twelve years he has studied the problems of amyloid disease and in four cases he has not only demonstrated the presence of this condition during life by associated pathological and anatomical means but has also seen it disappear and the patient recover He adopted Arnold Josefson's system of biopunctures but found that when the liver was explored with a fine needle the hepatic cells aspirated were always healthy even when the patient was undoubtedly suffering from amyloid disease He found it necessary to withdraw by puncture a piece of liver as large as a liver acinus one with a diameter of 1 or 2 mm and a length of about 2 cm For this purpose he used a needle with a cutting edge throughout its circumference During the past twelve years 28 cases of amyloid disease have been observed in his wards and 34 biopunctures followed by a microscopical examination, have been performed In all but two cases the patients suffered from open tuberculosis complicated by a mixed infection In one of the two exceptional cases there was tuberculosis uncomplicated by any mixed infection the other case was one of chronic septic empyema. A bacteriological examination of the mixed infection of fistulae revealed only streptococci or staphylococci, no specific organisms were identified The histories of the cases showed that the appearance of amyloid disease occurred on the average from one to two years after the development of a discharge The author has come to the conclusion that the diagnosis of amyloid disease merely on the strength of such clinical evidence as enlargement of the spleen and liver and the presence of albuminuria in a debilitated patient cannot be more than a probable diagnosis and that certainty can be achieved during life by exploratory puncture By repeating the process it is possible to follow the onset diminution and disappearance of this condition, it may disappear provided that the causative factors are eliminated even after the liver has become so enlarged that it extends to the iliac fossa An enlarged liver in a case of chronic suppuration may not necessarily be amyloid and amyloid disease may be found in a liver of normal dimensions The kidneys may be full of amyloid material without any albuminuria existing

Surgery.

123 The Etiology of Paget's Disease of the Nipple

ARTEP briefly describing the symptomatology and prognosis of Paget's disease of the nipple and J ROUSSET (*Journ de Chir* May 20th 1930 p 311) discuss its causation An account is also given of its pathological anatomy and of the so-called Paget cells, which the authors term dyskeratosic cells Basing their conclusions on a study of five cases of Paget's disease recently examined on studies of normal nipples of old women and on observations in cases of pre-epitheliomatous keratoses of other regions Massia and Rous et coll hold that the disease is of a cancerous nature The two usual theories of the etiology of the affection—namely that it is an epidermotropic cancer and that it is an autonomous disease—are narrated and various other theories (of Butlin of Dubring and Wile and of Wickham) are mentioned A study of these leads the authors to the view that only five solutions of the problem can exist One is that the disease is not of a cancerous nature and the cancerous degeneration is only a mere coincidence In the autonomous theory held by Darier and Civatte the affection is considered precancerous commencing independently and evolving more or less solely for some reason or other it is suddenly complicated by a cancer extending from a deep cancerous growth to the breast The third from an epidermotropic cancer (the old hypothesis of Thiry) maintained by Masson and Pautrier) suggests that the disease is an invasion of the skin by cancer of the mammary from a deep cancer A fourth solution is that the malady is a cutaneous cancer at its commencement and is afterwards propagated deeply These four hypotheses are criticized and rejected by Massia and Pousset who believe that the condition is a cancerous affection originating in the nipple it is later propagated at the same time to the skin by the epithelial tissues and to the deeper structures by the galactophores This cancer is moreover of special type since it

commences in a region normally dyskeratosic Reasons are given for this hypothesis, which its authors consider the most rational.

124 Rupture of the Tendo Achillis

J QUENU and STOIANOVITCH (*Rev de Chir*, No 10, 1929, p 647) report two cases of rupture of the tendo Achillis which were treated by *them with good results* There are three main causes of rupture—namely, when the tendon is cut by a sharp instrument or projectile, when the tendon is *ruptured by a sharp contraction of the* calf muscles, following an external trauma which, without dividing the soft parts, produces a rupture subcutaneously *The lesion occurs most frequently between the ages of* 30 and 50, often in stout men and athletes Rupture of the tendon is usually accompanied by a fall, it is supposed that during some rapid movement made to avoid falling the muscle contracts, and the tendon is ruptured while in an abnormal position Out of 68 cases under review only one was bilateral, *in every case the rupture was complete* The indications which lead to a correct diagnosis are the noise heard as the tendon ruptures, the intense pain which follows the fall, and *the immediate functional impotence* *Radiography in certain* cases is of value Repair of the tendon by means of a strong suture of the two extremities must be undertaken as soon as possible, *this is followed by careful post operative treatment* which consists of placing the foot in extension for three days, after which slight movements of flexion and extension are *encouraged in order to avoid the formation of adhesions.* Walking must not be allowed for at least eight or ten days

125 General Treatment of Cancer

W DRÜGG (*Med Welt*, April 19th, 1930, p 560) emphasizes the need for treatment of the general as well as the local condition in cancer patients He recalls the work of Warburg on the metabolism of such cases, showing that there is an abnormal output of lactic acid in the tumour cells in sufficient quantity to upset the reaction of the body fluids, and that the breaking down of protein stops at the albumoses, causing an intoxication of the whole body These metabolic failures account for the cachexia and also for damage to such organs as the liver, pancreas, and spleen, they also explain the disturbance of nutrition which occurs, even when the tumour is not in the digestive tract The question of diet is consequently of great importance The food must be easily assimilable but rich in calories, proteins, and fats, and carbohydrates should be given cautiously because of the risk of increasing the lactic acid, glucose is well tolerated and may be administered either intravenously or per rectum Insulin is recommended because of its influence on carbohydrate metabolism The excretory functions of the bowel and kidney must be carefully regulated to ensure the evacuation of toxins Drug treatment aims at influencing the tumour directly, or benefiting the organism as a whole Arsenic is useful for its blood building capacity, its effect on the basal metabolism, and its power of modifying pathological tissue Iron assists by increasing the haemoglobin, and quinine by limiting protein destruction Blaudity gives a pill containing ferrous sulphate, arsenious acid, and quinine sulphate, once daily, and continued for years with short breaks Iodine and calcium prevent fermentation, and silicic acid has a good effect on connective tissues In addition, change of air, baths, and light treatment may be beneficial

126 Bone Lesions in Lymphogranuloma Malignum

R MARZIANI (*Arch Ital di Anat e Istol Patol*, January–February, 1930, p 31), who records an illustrative case, states that though some examples of bone lesions in lymphogranuloma have been described, only a few have been studied anatomically, and most of them have been diagnosed as such by clinicians or radiologists without coming to necropsy Even when an anatomical examination has been performed a distinction must be made between those cases in which the bone lesion, usually exclusively situated in the medullary substance, was only discovered because a systematic examination was made of the bone, and particularly the medulla, without any clinical symptoms or gross anatomical changes having drawn attention to the skeleton, and those cases in which the clinical symptoms directed attention to the bones While the former are frequent, the latter, of which Marziani's case is an example, are rare His patient was a man, aged 28, who developed bone lesions first in the knee joints, and later in the clavicles ribs and cranium On clinical and x ray examination there was nothing to distinguish the condition from tuberculosis The necropsy showed diffuse lymphogranulomatosis of the lymphatic glands with osteo periosteal and renal and meningeal localization, degeneration of the viscera and dilatation of the heart This is the first case of lymphogranulomatosis on record in which the bone lesions were predominant at an early stage, and were the cause of death through meningitis

Therapeutics.

127 Ephedrine Sulphate in Acute Shock

C A JOHNSON (*Journ Amer Med Assoc*, May 3rd, 1930, p 1388) adduces by animal experiments and gives reports to show that intravenous injections of ephedrine sulphate are useful in the treatment of shock due to severe trauma or haemorrhage The advantages of this drug are said to be that it is relatively non toxic, has a pronounced haemodynamic action, as well as a marked stimulant effect on the central nervous system, and that it continues to act over a long period, allowing the body to recover from the loss of blood and enabling other and less rapidly acting forms of treatment to be instituted He cites four cases in which intravenous injections of 15 mg of ephedrine sulphate, followed sometimes by larger doses, in the course of a few hours were highly effective Johnson believes that in some instances the central nervous system depression seems to be the predominating factor, and the value of ephedrine sulphate in this connexion is strongly commended

128. The Acidity of Novocain Solutions

J JARZAB (*C R Soc de Biologie*, June 13th, 1930, p 618) remarks that in stomatology novocain and adrenaline are employed as anaesthetics in physiological solutions of sodium chloride In order to counteract the instability of the solution, due to the oxidation of the adrenaline, sodium phosphate or sulphate, hydrochloric acid, and thymol are often added These mixtures are acid, their *pH* ranging between 1 95 and 2 6 This acidity, which is necessary to maintain the novocain in solution, is harmful to living tissues, causing a complete lysis of the erythrocytes, it also lowers the anaesthetic power of the novocain, which is only manifest in a slightly alkaline medium Jarzab has endeavoured to improve the physiological saline solution as a solvent of the novocain by adding potassium chloride and bromide, sodium bromide, and calcium chloride in different proportions not harmful to the red cells He found that *the anaesthetic action of these preparations was not very* satisfactory, that better results were obtained by using only one salt, and that a 1 per cent solution of potassium chloride *was the most effective* A *preparation of novocain* and adrenaline with this solvent is slightly alkaline (*pH* = 7 4), is without injurious action on the tissues, and its anaesthetic power is *greater than that of novocain in simple physio*logical saline solution

129 Intensive Iodine Treatment of Diphtheria

BOUDREAU (*Journ de Méd de Bordeaux*, April 20th, 1930, p 301) assigns the name of "neo diphtheria" to those highly virulent and often serum resistant types of the disease which have been encountered recently, and advocates iodine medication, which he has previously found efficacious in various acute infections, including tuberculosis He claims to have adduced evidence that in many acute infective diseases, especially where the infection has been intense and apparently overwhelming, doses of iodine can be given without harm, and indeed frequently with life saving effect, the value of the treatment being far in excess of the usual therapeutic measures In his opinion iodine, used for its antibacterial and antitoxic actions, can safely be given in doses amounting to 100 drops daily for every year of the patient's age With regard to *virulent cases of diphtheria in particular*, he suggests a dosage of 10 drops, repeated every one, two, or three hours in the case of young infants, and of 20 to 40 drops in older children and adults In desperate cases he states that doses of a drachm or even more, five or six times a day, are well tolerated He advocates trial of the iodine method in all cases of diphtheria which are progressing badly, whether the reason be enfeebled natural resistance, exalted virulence of the disease, or reduction of the efficacy of the serum in use

130 The Effect of Pilocarpine in Sympathicotonia

THE gastro intestinal tract is innervated by both divisions of the vegetative nervous system, and its motility depends on a proper balance between the inhibitory sympathetic and the motor parasympathetic tonus *The term sympathicotonia* has been used by Danielopolu to designate a hyperactivity of the sympathetic innervation as compared with that of the parasympathetic E M LANDIS and J C GITTINGS (*Amer Journ Dis Child*, May, 1930, p 1022) report a case of this condition in a girl, aged 10, who had suffered severe attacks of epigastric pain beginning *at the age of 9 months, and* occurring on the average every two or three weeks The phenomena caused by stimulation of the sympathetic—namely, *dilatation of the pupils*, sweating, increase in the heart rate elevation of the blood pressure, diminution of the gastric

acidity, inhibition of the gastric and intestinal peristalsis diminution of the gastro-intestinal tonus, and increased tonus of the ileo-colic sphincter and pylorus—were all observed and there was leucocytosis with glycosuria The reaction to atropine and the marked sensitivity to adrenaline were the most significant observations in favour of the diagnosis of sympathicotonia Single attacks were aborted by intramuscular injections of physostigmine salicylate (1/60 grain) or intravenous injections of pilocarpine hydrochloride (1/40 grain) The oral administration of pilocarpine in doses of 1/48 grain, twice and later thrice, daily, was followed by complete relief from symptoms

131 Liver Treatment in Spinal Degeneration in Pernicious Anaemia

H LOTTIG (*Münch med Woch* May 16th, 1930, p 853) comments on the present conflicting opinions as regards the influence of liver on the spinal symptoms of pernicious anaemia He concludes that in some of the cases where nervous changes have commenced or have progressed during such treatment the patient was not receiving adequate amounts of liver In a series of nine cases of subacute combined degeneration which were carefully controlled by close observation, especially of the objective signs definite improvement was noted in six particularly referable to the posterior column lesions Of the remainder, two patients died from broncho pneumonia and one could not be kept under observation Recent cord changes are naturally more easily influenced by liver therapy but old standing cases *may be benefited Improvement seems to take place only* after the blood regeneration has reached a certain stage, and the nerve symptoms may even increase slightly at the commencement of the treatment The author points out the relative frequency of psychosis of a paranoic type in this disease, he states that this may develop during liver therapy, or be present before the treatment has commenced

Disease in Childhood

132. Tuberculous Meningitis in Children

TUBERCULOUS meningitis is the most common form of leptomeningitis in children, with the exception of epidemic outbreaks of the cerebro-spinal type there appears to be no difference in the incidence in the two sexes The disease is rare under the age of 6 months, is far more frequent in the second year of life than at any other period and a special tendency to this affection persists till the end of the sixth year though gradually diminishing in degree Prophylactic measures are therefore required more especially during these first five years H S SNYDERMAN (*Med Journ and Record* May 21st, 1930 p 508) states that there are two sources of tuberculosis in early childhood residence in close contact with tuberculous persons and the prolonged use of infected milk especially if not boiled Other causal factors may be trauma or *mental strain such as school work The typical* form of the disease presents three stages the stage of irritation, or of the prodromal symptoms that of pressure or the transitional stage, and the stage of paralysis or coma The onset is insidious and the early symptoms are little more than malaise In a few days vomiting apparently causeless occurs The presence of this vomiting with constipation and headache is always suggestive of tuberculous meningitis The child gradually becomes unnaturally drowsy and irritable, and the abdomen now begins to show the typical hollowed out appearance In a week or ten days after the onset motor disturbances become evident in a slight droop of one eyelid or a squint the pupils tend to contract and the neck is slightly stiff, but marked head retraction and opisthotonos of the rest of the spine are rare A fine tremor of the hands on movement and a tendency to deep sighing expirations at intervals are symptoms of great diagnostic value The progress of the disease is variable and remissions *are common When the third stage sets in* there is general muscular relaxation with difficult and often impossible deglutition The respirations become quicker and irregular the pulse rate increases, the temperature rises and a fatal result usually ensues from exhaustion and deep coma, or convulsions may develop and continue for twelve to twenty four hours terminated by death The diagnosis is often very difficult and depends on the results of a lumbar puncture, which is of essential importance The prognosis is exceedingly grave as the disease is almost invariably fatal If the diagnosis is *correct the* case is practically hopeless whatever treatment is employed As a positive diagnosis is not always possible all cases should be treated like other forms of meningitis Three cases are briefly reviewed by Snyderman to illustrate the absence of symptoms at the onset with the exception of the persistent, causeless vomiting

133 Meningococcal Meningitis in Infants.

C F MCKHANN (*New England Journ of Med*, March 13th, 1930, p 520) states that during a six year period ending November 1st 1929, the mortality rate in a series of 74 cases treated in the Infants and Children's Hospital Boston was *43 per cent The patients were divided into the following* three groups (1) Under 1 year, 39 cases, with 25 deaths, (2) 1 to 2 years, 10 cases, with 3 deaths, and (3) 2 to 12 years, 25 cases, with 6 deaths The mortality figures include deaths due to the infection in the acute stage complications, and sequels The results in the cases treated within the first week of the disease showed about the same percentage of recoveries in all three age groups, but when the illness had lasted longer than a week the mortality rate among the *infants ranged from 75 to 100 per cent* Although the acute symptoms frequently subsided under intensive treatment by injections of serum alternately into the ventricles and the lumbar subarachnoid space, death occurred later from chronic hydrocephalus McKhann concludes by emphasizing the importance of the early diagnosis of the disease in infants and the development of more effective treatment in later cases

131 The Growth of Infants receiving Undiluted Milk.

MARTHA VAN KIRK NELSON (*Amer Journ Dis Child*, April, 1930 p 701) records a study of nine male infants kept under close observation in a metabolism ward from the time they were 2 weeks old until they reached the age of 6 to 10 months *Each of the infants when 2 weeks old received 660 c cm of* milk (six 4-oz bottles) this amount being increased gradually to 900 or 1 000 c cm (four feeds each of 8 oz) at the age of 6 months Raw milk and corn syrup (6 per cent of the volume of the milk) were boiled vigorously for three minutes, and then cooled from 4 to 5 c cm of lactic acid, supposed to facilitate the digestion of milk, was added to each quart of milk 30 c cm of orange juice being given daily until the infants were 3 months old and 60 c cm daily thereafter Half a teaspoonful of cod liver oil was given until 6 weeks of age, and then one teaspoonful daily Egg yoke was added to the feeding mixtures at age periods ranging from 3 to 6 months Carrots were added at 6 months and prunes at 7 months both as purées After each feeding 10 to 20 c cm of distilled water was used to remove the curds adhering to the sides of the bottle, and these washings were given to the infant According to Finkelstein's formula the food intake of these infants should have been diminished by about one third, but not only were these feedings of undiluted milk actually well tolerated they produced a gain both in weight and in length, and a proportionate increase in the retention of nitrogen they did not therefore represent merely the accumulation of adipose tissue

Obstetrics and Gynaecology.

135 Exploratory Curetting of the Fundus Uteri

J L FAURE (*Presse Med* May 24th 1930 p 705) attacks the opinion generally held and formerly by himself also that exploratory curetting is necessary in all cases of suspected cancer of the body of the uterus, he defines such curetting as involving uterine dilatation, a methodical and complete exploration of the whole cavity, and consequently a general or spinal anaesthesia In certain cases where the uterus is more or less open and can be entered without difficulty, permitting the removal of cancerous debris without injury or appreciable pain a prudent exploration might be thinks, be useful It is pointed out that a woman past the menopause who suffers from prolonged haemorrhage or a doubtful discharge with a healthy cervix has *in a arly* every case cancer of the fundus an affection very slow but fatal radio-resistant and almost always curable by hysterectomy *If* not performed too late For curetting the same preparation is needed as for a radical operation if a preliminary one is performed to confirm an almost certain diagnosis there is an unnecessary loss of time with an increased limitation of the subsequent operation and anaesthesia moreover should an abdominal instead of a vaginal hysterectomy be decided advisable further time is lost in changing the patient's position If the curetting is positive and merely confirms the necessity for operation it is useless and may even be harmful If it is negative or doubtful the postponement for some days of the inevitable operation is harmful or may lead to the more dangerous decision no to operate and thus prevent the removal of a uterus which in the vast majority of cases is cancerous Faure therefore strongly advises the abandonment of exploratory curetting He maintains that the circumstances and clinical signs and symptoms should be the guide as to an operation or abstention therefrom

136 Vincent's Disease of the Vagina

C H ARNOLD (*Journ Amer Med Assoc*, May 10th, 1930, p 1461) reports a case in which infection of the vagina with the characteristic spirilla and fusiform bacilli of Vincent's angina appeared subsequent to a throat infection, and agranulocytosis was present similar to that found in other cases in which the throat alone was infected Arnold remarks that the condition is contagious, and that, therefore, prompt and continued intensive treatment is necessary, together with the safeguarding of others from being infected The patient was treated with intramuscular injections of neoarsphenamine, and the vaginal patch received applications of a paste of this drug in glycerin Frequent douches with hot permanganate solution were given during the day The disease cleared up simultaneously in the mouth and the vagina, and an uninterrupted recovery ensued The author comments on the fact that women seem to show more tendency to severe infection by Vincent's organisms than do men, but cases of vaginal involvement seem to be exceedingly rare

137 Lateral Laparotomy in Ovarian Cysts complicating Pregnancy

WHILE the median abdominal incision is preferable in cases of ovarian cysts complicating pregnancy when the uterus is but slightly enlarged, and in those cases in which the cyst is not recognized till the end of gestation, and Caesarean section is necessary before removing it, V LE LORIER (*Bull Soc d'Obstet et de Gynécol de Paris*, April, 1930, p 234) points out that between the fourth and eighth months of pregnancy the conditions are very different The large size of the uterus then necessitates an operation, even for small retro uterine cysts This involves a very long incision, which seriously lessens the subsequent resistance of the wall, while the bending forward of the uterus entails the risk of premature labour To avoid these disadvantages a lateral laparotomy is advised The incision is made two inches inside the antero superior iliac spine across the aponeurotic planes, the reconstitution of which is easy and forms a firm wall which is capable of withstanding both the distension of the uterus, if pregnancy be continued, and a premature labour Since only the volume of the cyst has to be considered, a long incision is not necessary, one of 10 cm is usually sufficient, though a longer one can easily be made if necessary The incision falls on the vascular border of the uterus in the region of its lower segment The cyst can easily be reached by introducing the hand behind the uterus, which need not be displaced or injured, the cyst can also be easily punctured, if desired, the peritoneum being very effectively protected The treatment of the pedicle is remarkably simplified, since it is exposed to view Not the least important consideration is that by this method the uterus is subjected to a minimum of displacement and handling, thus lessening the danger of premature labour Seven cases of ovarian cysts complicating pregnancy are recorded, in which lateral laparotomy was employed with most satisfactory results

Pathology.

138. The Action of Saline Waters on Isolated Heart Muscle.

A MOUGLOI and V AUBERTOT (*Paris Méd*, May 10th, 1930, p 438) record observations on the contractions of the isolated heart of *Helix pomatia*, as recorded on a drum The optimum solution for ventricular function was NaCl 6 5 grams, KCl 0 14 gram, CaCl 0 12 gram, $NaHCO_3$ 0 01 gram, NaH_2PO_4 0 01 gram, and water 1,000 c cm The first series of spa waters tested was the sulphate group, Miers, Montmirail, Decize Saint-Are, and Contrexeville Pavillon, these were diluted with Ringer's solution, distilled water, or glucose Their action was found to be constant, and there was no modification of rhythm, but a considerable increase of tonus, itude was decreased by partial abolition of the diastolic ssion A return to Ringer's solution re established ormal rhythm The next series investigated was the Arbonate waters Pougues water immediately arrested he heart s action, but the normal beat was resumed on returning to Ringer's solution Châtel Guyon water in pure olution arrested cardiac contraction, and when diluted with lextrine it resulted in an arrest in hypertonus, in either vent the return to normal with Ringer s solution was delayed Vichy water diluted with an equal part of Ringer's olution caused an increase of tonus, a slowing of rhythm, nd a diminution of the amplitude Saint Nectaire water diluted with an equal part of Ringer's solution arrested the rhythm in hypotonus Royat water, in pure form, caused an arrest in hypertonus, in isotonic solutions the contractions were still arrested The authors discuss the mechanism of these results, remarking that radio activity can be eliminated as these bottled spa waters had been kept open for some time They conclude that spa waters increase myocardial tonus by their anions, SO_4 and HCO_3, act indifferently through their light cations, Na, Ca, and Mg, and decrease nerve conductivity by virtue of their heavy cations, notably Fe

139 Fluctuations in Susceptibility to Encephalitis

C LEVADITI, P LEPINE, and R SCHOEN (*C R Soc de Biologie*, May 16th, 1930, p 175) have attempted to modify the resistance of rabbits to encephalitis virus by treating them with certain drugs having a profound constitutional effect Some rabbits were given 50 per cent alcohol by the mouth, others were injected intravenously with the hypnotic somnifen or with the hormone thyroxine, others were given irradiated ergosterol The particular substance used was administered on four to seven occasions, and the rabbits were then inoculated intracerebrally with a glycerinated suspension of a strain of encephalitic virus that had become practically avirulent Irradiated ergosterol, even though it caused progressive emaciation, had no apparent effect on the resistance of the animals On the other hand, alcohol and somnifen given in doses sufficient to produce profound hypnosis, and thyroxine given in doses sufficient to produce rapid wasting, increased the susceptibility of the rabbits considerably, most of the animals died in about a week, with positive histological findings, and from many of them the virus was passed on successfully to normal rabbits A number of the control rabbits contracted encephalitis, but this was ascribed to the fact that they were inoculated with a mixture of several strains The authors conclude that certain drugs, which act on the nervous system directly or on the general metabolism, are able to increase the susceptibility of rabbits to the encephalitic virus They suggest that the seasonal periodicity of certain infectious diseases may be due to the occurrence of changes similar to those produced experimentally

140 The Production of Stone in the Bladder

R MCCARRISON (*Indian Journ Med Research*, April, 1930, p 1101) records the results of a series of experiments on rats which he made in order to ascertain whether lime exercised any influence in favouring the production of vesical calculi These showed that the ingestion of lime in excess of requirements, by rats fed on a diet deficient in suitable protein, fat soluble vitamins, and vitamin C, exercises an influence which markedly favours stone formation This conclusion conforms to the widespread belief that the continued consumption of hard water is favourable to the formation of stone It would seem, however, that this effect will not be produced in the presence of a properly constituted diet In further experiments (ibid, p 1103) this investigator found that certain cereal grains favoured the production of stone in rats These, in the order of their potency, were wheat, oats, rice, millet, and cambu Millet and rice have approximately the same degree of stone forming potency, both are less potent than oatmeal and much less potent than whole wheat flour Still further experiments (ibid, p 1115) showed that, in a stone producing diet, the replacement of linseed meal by butter afforded the rats protection against not only urinary calculi, but also against the anaemia, the gastro intestinal disease, the asthenia, and the broncho pneumonia, from one or other of which certain animals, not receiving butter, suffered and died McCarrison has previously reported that the addition of whole milk to a stone producing diet prevents the formation of urinary calculi in rats

141 Functional Tests of the Liver

H G MOGENA (*Arch de med, chir y esp*, May 17th, 1930, p 528) remarks that owing to the complexity of the functions in which the liver is concerned there is not at present a definite test of the insufficiency of the hepatic function as a whole The tests in use indicate only the insufficiency of some definite function In Mogena's experience the most important clinical tests at present concern (1) hyperbilirubinaemia, delay in the elimination of a small quantity of bilirubin injected into the general circulation indicating a lesion of the hepatic cells, (2) galactosuria or glycaemia, the curve being plotted after the administration of galactose, and variations indicating disturbances in the glycogenic function of the liver, and (3) the time of disappearance from the blood of a colouring reagent such as phenolphthalein or rose of Bengal, or the time when it appears in the bile obtained by duodenal intubation This test indicates the antitoxic function of the liver

PERCAINE "CIBA"

Trade Mark Registered

The New Local Anæsthetic for Regional, Infiltration, Surface and Spinal Anæsthesia

Acts in extreme dilution (0·5—2 1000)
Produces anæsthesia of unattained intensity and duration.
Not a narcotic. Economical in use.
Belongs chemically to a class entirely different from cocaine and its derivatives

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombieres treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payments. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.

Tel.: 64117. *For terms etc., apply to the Medical Superintendent.*

BELVOIR NURSING HOME,
ASTON-ON-TRENT, DERBY.

FUNCTIONAL NERVOUS DISORDERS & CHRONIC MEDICAL CASES.

The Home, a Georgian mansion, 14 miles from Nottingham and 6 miles from Derby, is for both sexes. In addition to the methods of general medicine, Psycho-Therapeutic treatment is used extensively in suitable cases. Certifiable cases are not received. Electrical treatment, Radiant Heat, X-ray, and Ultra-violet Light is available in the Nursing Home. Billiards, tennis, etc. Fees from 5 to 12 guineas per week; for Chronic Medical Cases from 3 guineas a week. For further particulars apply to—

Dr. E. M. DOUGLAS MORRIS, ASTON, DERBY. *Telephone*: Shardlow 16.

County Council of Durham.

DISTRICT TUBERCULOSIS MEDICAL OFFICER

The County Health Committee invite applications for a District Tuberculosis Medical Officer, at a commencing salary of £900 per annum rising by annual increment of £25 to £700 per annum. Travelling expenses will be paid by the County Council.

The appointment will be held subject to three months' notice on either side, and to the following conditions:

(1) The officer appointed must be a registered Medical Practitioner between the ages of 25 and 45 years, must devote the whole of his time to the duties of the office, and must not engage in private practice.

(2) He should either have held a previous appointment as Tuberculosis Medical Officer with the approval of the Minister of Health or

(i) Have had at least three years' experience in the practice of his profession,

(ii) Have spent in general clinical work a period of not less than eighteen months, of which not less than six months have been spent in a Hospital as Resident Officer in charge of bed occupied by general medical or surgical cases, and

(iii) Have received special training for a period of not less than six months in the diagnosis and treatment of tuberculosis.

(3) He will be attached to the County Health Department, and will, subject to the directions of the County Medical Officer be under the control of the Central Tuberculosis Medical Officer.

(4) He will be required to reside in his Dispensary area or such other centre as required by the Council.

(5) He will be required to carry out the duties of a District Tuberculosis Medical Officer.

(6) He must be prepared if called upon to act as Locum Tenens to other members of the Medical Staff of the County Medical Officer.

(7) The holding of a Diploma in Public Health, and practical experience in bacteriological laboratory work will be deemed additional qualifications for the post.

The candidate appointed will be required to pass the County Council's medical examination, and will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

Applications endorsed "District Tuberculosis Medical Officer," with copies of not more than three recent testimonials, must be forwarded on or before August 16th next to the County Medical Officer, Shire Hall, Durham, from whom forms of application can be obtained.

Shire Hall, Durham. July 28th 1930

HAROLD JEVONS, Clerk of the County Council.

Lindsey County Council.

ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH.

Applications are invited for the post of Assistant County Medical Officer of Health.

The person appointed will be required to act as an Assistant Tuberculosis Officer and School Medical Inspector. He will also be required to take charge of a Venereal Disease Clinic and act as Medical Officer to a Tuberculosis Hospital of 12 beds.

The appointment will be made in accordance with the Local Government (Qualifications of Medical Officers and Health Visitors) Regulations 1930.

The salary will be at the rate of £600 rising by annual increments of £25 to £700 with an allowance for travelling on the County Council's scale.

Particulars of appointment and forms of application may be obtained from the undersigned. Applications to be received not later than August 23rd.

W. S. H. CAMPBELL, County Medical Officer of Health.

Public Health Dept., County Council Offices, Newland, Lincoln. July 26th, 1930

Swansea County Borough

RESIDENT MEDICAL OFFICER

INFECTIOUS DISEASES HOSPITAL

The Council invite applications for the above appointment from duly qualified unmarried Medical Practitioners. The salary will be at the rate of £350 per annum together with emoluments. Previous experience in an Infectious Disease Hospital is desirable.

Applications (on special forms with particulars of duties) can be obtained from the Medical Officer of Health, Public Health Offices, Swansea, to be sent in not later than August 9th.

County Borough of Darlington.

HEALTH VISITOR

The Corporation invite applications for the appointment of Health Visitor.

Applicant must hold the following qualifications:

(a) the new Health Visitor's Certificate of the Royal Sanitary Institute, or

(b) the Certificate for Health Visitors prescribed by the Board of Education Regulations of 1919, or

(c) have held a post as Health Visitor approved by the Ministry of Health.

The duties are chiefly concerned with maternity and child welfare, and the successful applicant will be required to carry out such duties under the direction of the Medical Officer of Health.

The salary for the appointment (under the Corporation's scale) as at present adjusted by reference to the rise or fall in the cost of living is £172 16s., and is subject to such other conditions of such scale as are applicable, and additional allowances amounting to £11 in respect of travelling and uniform are made.

The salary is subject to a deduction of 5 per cent. under the Local Government and Other Officers' Superannuation Act, 1922, and the successful applicant will be required to pass a medical examination.

Applications, stating age, qualifications, and experience, must reach the Medical Officer of Health, Feetham, Darlington, not later than Monday, September 1st.

Town Clerk's Office, Darlington. July 25th, 1930

H. HOPKINS, Town Clerk.

Town Hall, Bradford. July 31st 1930

N. L. FLEMING, Town Clerk.

County Borough of West Ham

DEPUTY MEDICAL OFFICER OF HEALTH.

Applications are invited from duly qualified registered Medical Practitioners for the post of Deputy Medical Officer of Health at a commencing salary of £650 per annum rising by annual increments of £50 to £1,000 per annum.

The engagement will be subject to three months' notice on either side.

The person appointed will be required to devote his whole time to the duties of the office, and to work under the direct supervision and control of the Medical Officer of Health.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and to a medical examination as required by the Council for the purposes of the Act, and the statutory contributions to the Superannuation Fund under the Act will be deducted from the salary.

Candidates should possess the Diploma in Public Health and have had experience in the general administration of a Public Health Department. It will be considered an advantage to have had special experience in one or more of the following:

(a) Maternity and Child Welfare.
(b) Infectious Diseases.
(c) Tuberculosis.
(d) Mental Deficiency.
(e) Medical Inspection of School Children.
(f) Poor Law.

Application must be made on the prescribed form, which may be obtained from the undersigned and returned accompanied by not more than three recent testimonials on or before August 23rd.

Canvassing Members of the Council is prohibited and will disqualify.

Town Hall, West Ham, E.15. July 23rd, 1930

CHARLES E. CRANFIELD, Town Clerk.

Borough of Leigh

ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER

The Town Council of Leigh invite applications for the appointment of Assistant Medical Officer of Health and Assistant School Medical Officer for the Borough.

The appointment will be subject to the approval of the Minister of Health and the Board of Education.

The person appointed must devote the whole of his time to the service of the Corporation and will be required to act under the supervision of the Medical Officer of Health and School Medical Officer.

The officer will be required primarily to carry out work in connection with the School Medical and Maternity and Child Welfare Services and in addition to undertake such duties in connection with the Public Health Services of the Borough as may be assigned to him.

Preference will be given to applicants who have had experience in ante-natal and midwifery work, administrative experience in the testing of sera and vaccines and in school medical work generally.

The salary will be £630 per annum, increasing by annual increments of £25 to a maximum of £700.

Applications, stating age, experience, and qualifications, accompanied by copies of not more than three recent testimonials, and endorsed "Assistant Medical Officer," must reach me not later than Saturday, August 16th.

Town Hall, Leigh (Lancs.)

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(FOUNDED 1880.)

12, Stratford Place,
Oxford Street, W.1.

Tele. Address: Triform, Wesdo—London.

Telephone: Mayfair 1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

Ingoing Partner should be about 30, English or Scotch, and married or about to become so.
8. YORKS.—In a clean and thriving manufacturing town, old-established non-panel PRACTICE, partly Homœopathic, and held 50 years by Vendor who is retiring. Cash receipts average about £2,400 p.a. Patients better and middle class. Midwifery refused. Good house, rent £100 p.a. Premium only 1 year's purchase, part down and balance by arrangement.
9. DERBYSHIRE.—Good mixed class unopposed PRACTICE, in very picturesque surroundings, within easy reach of good town. Gross cash receipts for past twelve months £900, including panel of 476. Fees 3/6 to 7/6, medicine extra. Suitable house, with 2 reception, 5 bedrooms, etc. Half an acre of garden. Rent on lease £70. Excellent sport and schools. Premium £1,200 or near offer.
10. BORDERS OF BERKS AND HANTS.—In a delightful district, an old-established mixed class PRACTICE averaging for the past three years £904 p.a. (last year £973), including panel of 400. Visits 5/- to 12/6, medicine extra (3/6). One opponent. House contains ample accommodation (2 sitting rooms, 7 bedrooms, bathroom, etc.). Large garden and garage. Rent £50 p.a. Prem. £1,400. Excellent sport.
11. DEATH VACANCY.—BRISTOL SUBURB.—Well-established non-panel, non-dispensing upper and middle class PRACTICE, averaging about £600 p.a., but capable of good increase. Suitable house can be bought or rented. Premium one year's purchase, or near offer.
12. YORKSHIRE.—GOOD TOWN.—PARTNERSHIP.—A one half share (guaranteed to produce £2,000 p.a. in first year) is offered in a good middle class PRACTICE. Income for the immediate past twelve months approximately £4,000. Small selected panel of 430. One appointment worth nearly £650 p.a. Fees 3/6 upwards. Opposition not strong. Suitable house can be bought or leased. Very good educational and sporting facilities. Premium 2 years' purchase.
13. NEAR HEREFORDSHIRE BORDER.—HOSPITAL TOWN.—Old-established mainly good class non dispensing PRACTICE, averaging about £1,200 p.a. Panel of 500-600. Fees 5/- to 10/6. Nice house in centre of town. Price for freehold £1,200, part on mortgage. Premium £1,800, £1,300 down and balance by instalments. Up to-date Cottage Hospital, and good scope for surgery.
14. YORKS.—PARTNERSHIP.—Within a few miles of large residential town, the half share of old-established unopposed country PRACTICE, owing to retirement of senior partner through age and indifferent health. Cash receipts for past three years average over £2,500 p.a., including appointments and panel of 1,200. Very little midwifery. Railway station. Good house available, with large garden. Electric light and water laid on. Price freehold £1,200, part on mortgage. Premium 2 years' purchase.
15. PARTNERSHIP.—COUNTY TOWN, within 150 miles North of London. A one fifth share is offered in a very old established good mixed-class Practice having good scope. Gross cash receipts for past twelve months nearly £6,000, including panel of 3,400. Fees from 4/-. Not much midwifery. Suitable house available. Prem. 2 yrs' pur.
16. WEST OF ENGLAND.—In a small pleasantly situated town amidst beautiful surrounding country, old established PRACTICE. Income nearly £1,350 p.a., including panel of 900. Visits 5/- to 21/-. Little midwifery. Very attractive house in own grounds of 2 acres, 3 large professional rooms (separate entrance), 2 reception, 5 bedrooms, bathroom, etc. Vendor's freehold. Price £2,400 (£1,800 can remain on mortgage). Premium £2,000. Good society, etc.
17. SHEFFIELD.—Old established mainly better- and middle class non-panel PRACTICE. Average income £700, but large scope. Appointment of £160. Fees 5/-, 5/- to 15/-. Excellent house with small garden. Ground rent £9. Premium for house and Practice, £1,250.
18. PLEASANT CATHEDRAL CITY, within 200 miles North of London.—Old established mixed class PRACTICE, averaging £1,600 p.a., including £800 from panel and over £100 from clubs. Visits 5/- upwards (occasionally 2 gns.) Very little midwifery from 2 to 5 gns. Large attractive house, with garden. Rent £80. Prem. 1½ yrs.' pur.
19. ESSEX.—Unopposed PRACTICE in very pleasant agricultural district, averaging £872 p.a., including panel of nearly 500, and appts. worth £140. Fees 3/6 to 10/6. Mid. 3 to 6 gns. (about 12 cases). Commodious house, with 2 reception, 5 bedrooms, and good professional accommodation. Large garden. Garage. Rent on lease £60. Good sport and schools within reach. Premium 1½ yrs.' pur.
20. LANCS.—Pleasant Town, near open country.—Well-established middle- and better class PRACTICE. Cash receipts last year over £980, including panel of 900. Visits 3/6 to 7/6, medicine extra. Mid. 2 to 10 gns. (about 20 cases). Suitable house, with 2 reception, 4 bedrooms, etc. Price for leasehold £1,100, £600 on mortgage. Premium 1½ years' purchase, part by instalments.
21. GLOS. — COUNTRY PRACTICE. — Old-established PRACTICE in picturesque surroundings, averaging about £1,250 p.a., including panel of over 1,100. Visits from 3/-. Commodious house, with 3 reception, 6 bedrooms, etc. Garden. Garage. Price for freehold £1,500, £1,000 on mortgage. Premium £1,850.
22. LONDON, SOUTH-WEST.—Very old established non-residential PRACTICE, averaging about £4,000 p.a. Panel of 1,500, but large scope for more. Fees 2/6 upwards. Suitable house or flat can easily be obtained to meet purchaser's requirements. Rent of surgery on long lease £100 p.a. Premium 1½ years' purchase.
23. LANCS.—LARGE TOWN.—Very old-established good industrial class PRACTICE, producing £2,500 p.a., including panel of 1,804, and appts. worth about £120 p.a. Fees 2/6 upwards. Very suitable for two friends in partnership, as two houses available. Good sport and schools. Premium 1½ years' purchase. A one-half share will be offered with view to succession in six or twelve months if desired.
24. CHESHIRE.—Industrial Town within easy reach of Manchester.—Well-established PRACTICE producing £2,600 p.a., with panel of 2,870. Fees 2/6 to 3/6, medicine extra. Good house, with ample accommodation. Price £1,000, or would be rented at £70 p.a. Premium 1½ years' purchase, half down and balance by instalments.
25. SOMERSET COAST.—PARTNERSHIP.—In a small increasing seaside resort, the five-twelfths share of a very old-established PRACTICE, producing last year £1,600, but offering exceptional scope. Panel brings in £480, and appointments. Visits 5/- to 4 gns. Mid. 4 to 6 gns; only about 12 cases yearly. Choice of 2 suitable houses (price freehold £950), with gardens. Electric light and gas. Premium 2 years' purchase.
26. SOUTH DEVON.—COUNTRY PRACTICE, steadily increasing, and situated in very pleasant agricultural district, within easy reach of coast. Gross cash receipts for past 12 months £2,326. Panel produces, with mileage, about £420. Fees 3/6 to 21/-. Only about 20 cases of midwifery from 2 to 5 gns. Suitable house, in main street, with 2 recep., 5 beds., etc. Garden. Garage. Rent on lease £50 p.a. Good sport. Prem. £2,800. Suitable two friends if wished.
27. SOUTH OF ENGLAND (Thriving Seaport Town, pop. over 30,000).—Old-established mixed-class PRACTICE. Income last year £623, but offering exceptional scope. Panel of about 430 and 2 small appts. Visits 3/6 to 5/-. Very attractive residence, with professional rooms, 2 reception, 4 bedrooms, bathroom, etc. Pretty garden. Garage. Rent on lease £100 p.a. Premium 1½ years' purchase.
28. YORKS (NORTH RIDING).—In a small pleasant market town, with pretty and prosperous surrounding country, very old established mixed-class PRACTICE averaging £1,247 p.a., including appts. worth £80 and panel producing last year £366. Visits 3/6 to 25/-. One opponent. Good house, facing south (3 reception, 5 bedrooms, bathroom, etc.). Garden. Garage. Electric light. Vendor's freehold. Price £1,350 (£1,000 on mortgage), or would let for few years at £80 p.a. Premium £1,500. Educational and social amenities.
29. KENT.—Pleasant Seaside and Residential Town (pop. 17,000).—Old-estab. non-dispensing middle and working-class PRACTICE, averaging for the past 3 years over £1,050 p.a. including transferable appt. worth about £200 and panel of 500. Visits 3/6 to 10/6. House contains 8 rooms, kitchen, bathroom, etc. Garden. Garage. Price freehold £1,500, but might be rented. Premium £1,500.
30. MANCHESTER.—PRACTICE is situated in a growing district offering very large scope. Income about £1,700 p.a., including panel producing £430. Fees 3/6 upwards. Excellent detached house, well situated, with 3 reception, 5 bedrooms, etc., all in good order. Price £1,800. Premium 1½ years' purchase.

Full Schedule of Terms and Conditions will be forwarded on application.

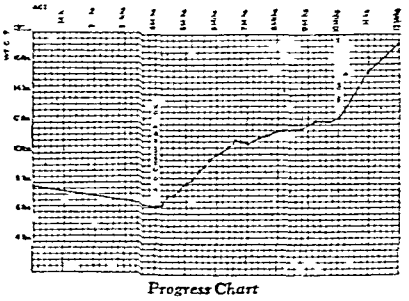
NATURALLY RICH

IN VITAMIN "D"

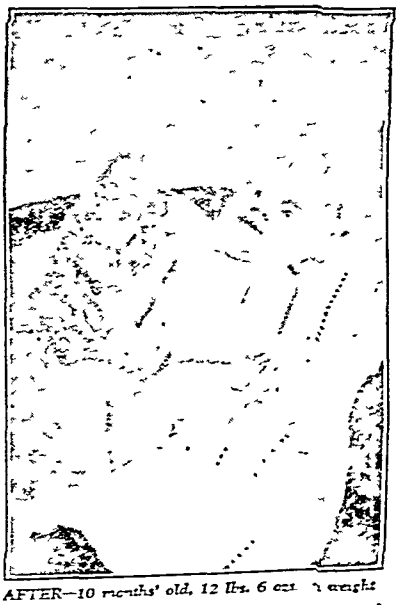
A "RESURRECTION"

GUILDFORD
30 6'30



"Baby Hook, came under my care shortly after birth suffering with marasmus following whooping cough. Broncho-pneumonia developed and was with great difficulty cleared up, leaving the child in a very low condition. Feeding proved a difficult problem, several things were tried without beneficial results. The results with Cow & Gate were truly wonderful, indeed it is a case of 'a resurrection.'"

(Signed)..... M.B.Ch.B.



Lacidac (separated) and Brestol, the Cow & Gate Humanised Cream, were used in the early days of treatment. Cow & Gate Full Cream and Brestol being used subsequently.

BEFORE—4 months' old, 6 lbs. 9 ozs. in weight.

Progress Chart

AFTER—10 months' old, 12 lbs. 6 ozs. in weight

June 1930. Baby Hook has now won a prize in a Baby Competition!

Write for literature and clinical samples of Lacidac and Brestol

BILIARY STASIS AND GALL-BLADDER DISEASE

It is stated that ten per cent. of our entire adult population suffer from gall-stones. As gall-stones, presumably, always follow infective inflammations, cholecystitis must be even more common. The relative frequency with which the gall-bladder is infected, on the one hand, by the bile received from a liver whose detoxicating capacity has been lowered, and, on the other hand, directly by the blood supplied through the cystic artery, is not determined; but, in either case, biliary stasis is a prominent aetiological factor in actual gall-bladder disease. The importance of promoting more active intestinal peristalsis and a hastened biliary flow is therefore obvious. Through the force of osmosis, the flow of bile into the intestine may, as the duodenal tube has revealed, be stimulated by suitable saline draughts, of which Eno's "Fruit Salt" is perhaps the most agreeable and most generally useful. It is suggested that many early cases of cholecystitis—apt to be cursorily dismissed with the vague diagnosis "dyspepsia"—might be arrested by such simple means as increased exercise and regular morning draughts of Eno's "Fruit Salt."

Eno is chemically pure, and free from all trace of the nauseous mineral sulphates—Glauber and Epsom. It contains no sugar or artificial flavouring.

"The Doctor's Emergency Reminder."

The Proprietors of ENO's "Fruit Salt" will deem it a privilege to send to any member of the Medical Profession a copy of the latest of their series of "Medical Reminders"—with or without a bottle of their preparation as desired. "The Doctor's Emergency Reminder" summarises briefly a few points in connection with the treatment of poisoning and various other emergency cases. It is bound in black morocco limp to conform to the style of the previous publications in this series.

Immunogens

IMMUNOGENS represent a class of bacterial antigens developed in the Medical Research Laboratories of Parke, Davis & Co. In their preparation, live virulent organisms are extracted for a short time with physiological salt solution immediately on being taken from the culture medium on which they have grown. Being merely washings of the bacteria and not the bacteria themselves nor the culture medium in which they have developed, Immunogens contain much less protein than any other antigen used for similar purposes, and are practically free from toxin.

Two types of Immunogens are issued, those prepared from one species of organism only, and those prepared from secondary infecting organisms in addition to the principal infecting agent; the title "Immunogen, Combined" is applied to the latter type.

Laboratory and clinical data indicate that Immunogens possess certain advantages not possessed by other antigens and that they probably constitute an advance in immuno-therapy.

The following Immunogens are available

CATARRHALIS *(Combined)*	PERTUSSIS	STAPHYLOCOCCUS
GONOCOCCUS	PERTUSSIS *(Combined)*	STREPTOCOCCUS
GONOCOCCUS (Combined)	*PNEUMOCOCCUS*	*STREPTOCOCCUS (Combined)*
	PNEUMOCOCCUS *(Combined)*	

In 10 cc. rubber-capped vials. Further particulars will be supplied on request.

Inflammatory Lesions of the Cervix-Uteri

PROBABLY the most common site of disease in the female genital tract is the Cervix-Uteri.

Despite the recognition of *Cervicitis* as a clinical entity, necessitating treatment, the therapy to be employed is still under dispute.

However, in selected cases, it has been found that the induction of Hyperæmia is a standard method of treatment.

Antiphlogistine

combines continuous *Moist Heat* with the osmotic and bacteriostatic action of glycerin, together with other synergistic agents, which bring about a neurovascular reflex, with a resultant active hyperæmia.

Fresh blood contains nutritive elements, vitamins, oxygen, leucocytes, immunizing bodies and enzymes. Such induced hyperæmia promotes a tissue drainage, which removes accumulations of altered cell metabolism and functional products. A normal supply of blood carries away organic debris, exudates and extravasations.

Write for a copy of our new brochure "Gynaecological Hints," together with sample of Antiphlogistine.

DEMONSTRATIONS OF PHYSICAL SIGNS IN CLINICAL SURGERY

By HAMILTON BAILEY, F.R.C.S.(Eng.), *Surgeon, Dudley Road Hospital, Birmingham.*

The illustrations have been still further improved and increased in number for this edition.

LANCET.—"This excellent book has been enlarged. Many new pictures have been added, and they are of the high standard of the rest. Mr. Bailey must be congratulated on the production of a work which gives just that assistance which is needed by the medical student attending his first clinics. It has won deserved popularity, and we predict for it a long and successful life."

BRIT. JOUR. SURG.—"An admirable book which we can recommend to all students."

JUST PUBLISHED.

Large 8vo. 184 pp. With 63 Original Illustrations. 17s. 6d. net. Postage 6d.

CANCER of the LUNG AND OTHER INTRATHORACIC TUMOURS

By MAURICE DAVIDSON, M.A., M.D., B.Ch.(Oxon.), F.R.C.P.(Lond.), *Physician to the Brompton Hospital for Consumption and Diseases of the Chest, and Dean of the Brompton Hospital Medical School, etc.*

FROM THE FOREWORD BY ARTHUR J. HALL, M.A., M.D., D.Sc., F.R.C.P., *Professor of Medicine in the University of Sheffield*

"If the practitioner is aware of the varied and insidious disguises which early pulmonary cancer may assume and if he knows what steps must be taken to unmask them, it rests with him by acting upon such knowledge, to help more than anyone else in forwarding advance in the treatment of this grave disorder."

"The Rose Corset-Belt"

for Accurate Abdominal Support and Comfort

EXTRACT FROM THE "BRITISH MEDICAL JOURNAL," DEC. 10th, 1927—

"Visceroptosis is the cause of so much discomfort and ill-health . . . and an ill-fitting or wrongly applied belt or corset may aggravate rather than diminish the subjective effects of this condition. . . . MADAME ROSE has for many years devoted special attention to this problem, and we have good reason to believe that she has given help and comfort to a considerable number of sufferers. We have received assurances from medical men, who have sent patients to her, that she gives personal attention to each patient, that she takes great care in adapting and adjusting the support to the particular needs of the case."

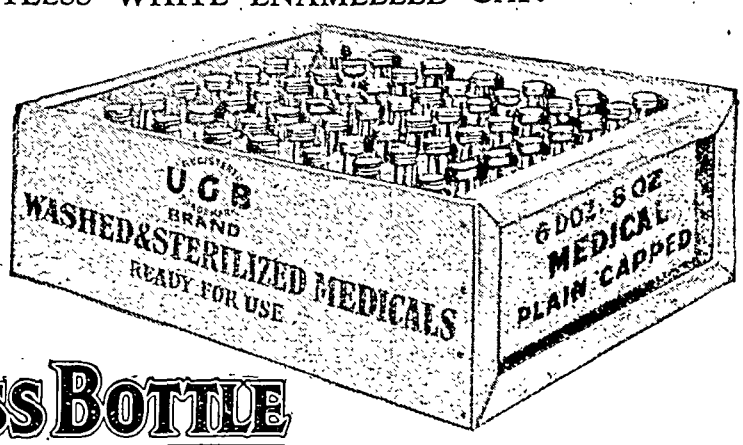
BRISTOL-MYERS COMPANY. 112, Cheapside. London. E.C 2



The U.G.B. MEDICAL BOTTLE Service

Photograph of actual package of Cork-mouth bottles with cover removed.

THE U.G.B. Washed and Sterilized medical bottle service—introduced early in 1929—has proved to be an unqualified success, so much so that we were recently compelled to increase the capacity of our washing and sterilizing plant.

The screw cap service is in particular demand, and owing to the preference of users for a cap in a neutral colour, we have now standardized in fitting the bottle with an attractive RUSTLESS WHITE ENAMELLED CAP.

Photograph of actual package of Screw-cap bottles with cover removed.

When is Diathermy of Value in Your Practice?

YOUR decision to use diathermy in the treatment of any condition will, of course, be based on recognized medical authority. Many doctors have become interested as a result of observing the many references to diathermy in current medical literature, and no doubt intend to investigate for themselves when opportunity presents. But a busy practice affords little of the time required in searching the files of the medical library, and it is put off indefinitely.

A preliminary survey of the articles on diathermy, published during the past year or so, is available to you in the form of a 64-page booklet entitled "Indications for Diathermy." In this booklet you will find over 250 abstracts and extracts from articles by international authorities, including references to more than a hundred conditions in the treatment of which the use of diathermy is discussed.

If you number yourself among the doctors who have not adopted diathermy in practice, and desire to investigate this form of therapy in view of reaching your own conclusion as to its value in your practice, you will find this booklet a convenient reference. A copy will be sent on request.

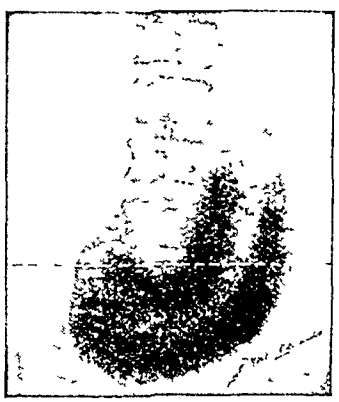
SALT'S PATENT GASTROPTOSIS CORSET

All the well-known features of Salt's Gastroptosis Belt are incorporated in this Corset.

This is an instance where, by supplying a special Corset, the necessity is obviated of the patient wearing a belt in addition to ordinary corsets.



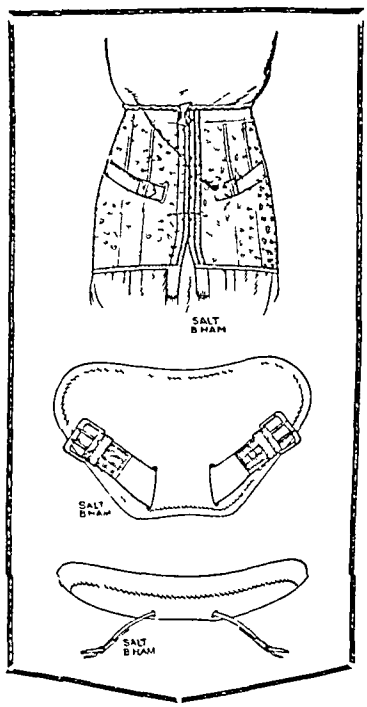


Fig A shows slightly dilated and much dropped stomach radiographed in the upright position immediately after partaking of a barium (6 oz) "Umbrose" meal The greater curvature projects 3½" below a line drawn between the iliac crests.

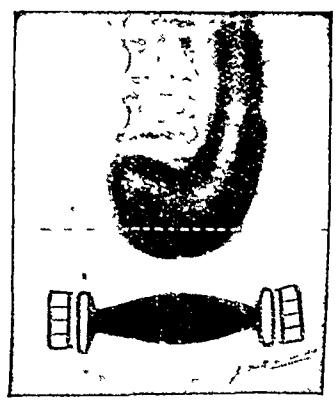

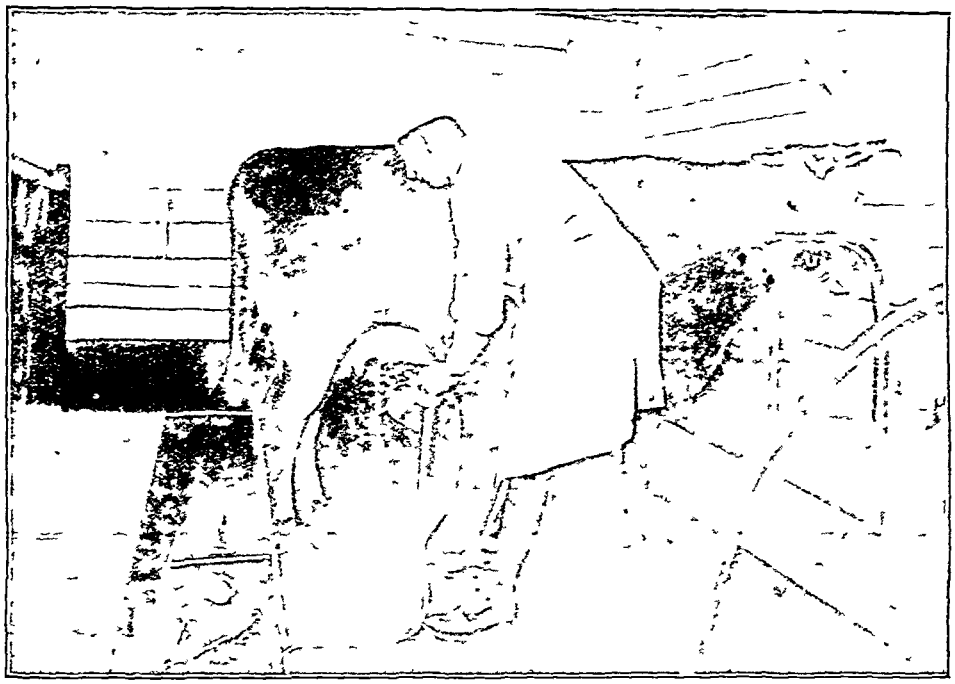

Fig B shows same stomach radiographed 15 mins later, the patient having lain upon a couch, the bottom feet of which were raised 9" The Belt was then applied, the patient allowed to walk about 5 or 6 minutes, and the radiograph taken in the upright position.

THESE ESSENCES PROVIDE RAPID STIMULATION AND RESTORE VITALITY . . .

•

WHEN SOLID DIET IS OUT OF THE QUESTION

A RECENT investigation showed that out of *every* 100 *doctors interviewed* 99 are recommending Brand's Essences for their patients.

These Essences can be swallowed without effort and rapidly absorbed by the digestive organs for they consist only of the pure essences of the finest meat conserved in natural jelly form. No substances are added—such as colouring matter, gelatine or preservatives, which could hinder assimilation.

Containing those properties of meat which excite the gastric secretions, Brand's Essences stimulate the digestive organs to instant activity. When illness leaves the patient in an exhausted condition, they restore vitality rapidly, and in convalescence they help to overcome the patient's intolerance of solid food by rousing the appetite.

Brand's Essences can be obtained at chemists and stores throughout the world in tins and glasses. On receipt of a professional card, samples will be sent to you immediately. Write Dept. F10, Brand & Co. Ltd., Mayfair Works, Vauxhall, S.W.8.

Wright's Coal Tar Soap.
Wright's Coal Tar Ointment.
Wright's Lysol.
Wright's Liquor Carbonis Detergens.

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique. Imitations will be found to be produced by simple digestion, usually accompanied by some primitive, perfunctory, and inadequate stirring; whereas, in the case of the genuine product, the intimate contact required, for the complete extraction of all the soluble antiseptic constitutents, is attained by a series of complicated processes, involving the use of highly specialized machinery.

WRIGHT, LAYMAN & UMNEY LTD., 66, Park Street, Southwark, S.E.1

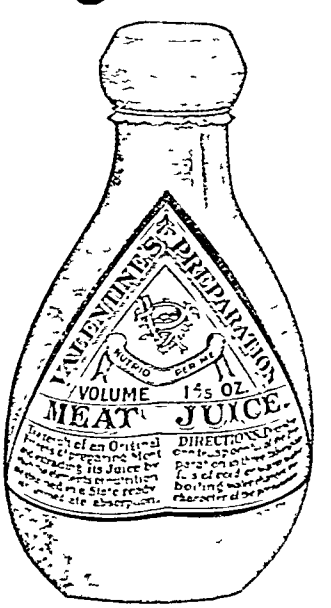
A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.

May we, therefore, venture to remind you of

DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.



We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.
It cannot harm the most delicate constitution and is at all times a safe and effective laxative.
Manufactured in London for the past 100 years.

DINNEFORD & Co. LTD.

MEDULLA RUBRA

BONE-MARROW IN ANAEMIA FROM HAEMORRHAGE

W. Borchardt (*Dt. med. Woch.*, March 28th, 1930, p. 521) records the results of his experiments on young dogs in which anaemia had been artificially produced by the removal of about half their blood. In the first series some of the animals were fed with rib-marrow others with marrow from the long bones. Control animals received a corresponding amount either of fat or of liver extract. The basal diet in each case contained a sufficiency of iron (6 mg. per cent.). Only the animals receiving the rib-marrow showed a definite increase of weight, and their haemoglobin formation was more rapid than that of the others. In the next series the experiment was repeated, but the iron content of the diet was reduced to 1·4 mg. per cent. The result was similar but more striking, the dogs receiving the rib-marrow regaining their haemoglobin far more quickly than the others.

THIS extract from the "Epitome of Literature," published in the "BRITISH MEDICAL JOURNAL," dated May 3rd last, is important as representing, in 1930, a complete justification of the formula upon which

Roboleine
THE FOOD THAT BUILDS THE BODY

has been produced without variation during the past twenty-five years.

The success of ROBOLEINE is thus due to intelligent anticipation and to consistently maintaining the highest possible standard of manufacture.

Medical Practitioners are asked to satisfy themselves of the merits of ROBOLEINE, for which purpose testing samples will be gladly sent upon request.

Successful Treatment of Hyperchlorhydria and Associated Conditions

"Alocol" (Colloidal Hydroxide of Aluminium) has proved remarkably successful in the treatment of hyperchlorhydria, gastric ulcer, fermentative dyspepsias with gastro-intestinal flatulence, acid eructation and other symptoms common to gastric disease.

The advantages of "Alocol" are that it actually removes from the system the causative acid radicle (Cl) instead of merely neutralising it, and so permitting reabsorption, accumulation and consequent recurrence of the symptoms of the disease.

Furthermore, "Alocol" neither hinders proteolysis nor causes destruction of any food element or factor. "Alocol" has a distinct healing and sedative effect; it promptly allays irritation by absorbing acid and other irritants.

Complete chemical history of "Alocol" with convincing clinical reports and supply for trial, sent free to physicians on request.

A. WANDER, Ltd., Manufacturing Chemists, 184, Queen's Gate, London, S.W.7.

Works KING'S LANGLEY, HERTFORDSHIRE M231

ALOCOL

Colloidal Hydroxide of Aluminium

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

"Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidal Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic and Sedative, "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

M 235

Infantile Diarrhoea.

A letter recently received.

The Medical Adviser of
Messrs. Kaylene Ltd.,
London.

Dear Sir,

The case to which I referred was a child of six months who was brought to me after having treatment elsewhere for diarrhoea and vomiting. The child was practically a skeleton and apparently had been vomiting everything—even medicines—for many days. The mother thought, and her friends thought, the child was dying, and I happened to be the nearest doctor. I gave the child one teaspoonful of plain Kaylene in plain, cold, boiled water, and kept the mother and child in my consulting room to watch effects. If ever a child was drawn from the jaws of death, I think that little sufferer was. The Kaylene was retained; the gasping steadily lessened; the haunting look of that child's eyes became less distressing; in fact, the change for the better was so pronounced that in an hour's time I allowed the mother to take the child home.

Fortunately, I had sufficient Kaylene by me (a sample you kindly sent), and I gave the mother sufficient to give a teaspoonful every hour during the night. The chemists' shops were all shut by this time. I gave full instructions—strict instructions—not to give anything else but Kaylene and plain, cold, boiled water as I had done.

In the morning the mother came to see me and informed me that only twice during the night the child had loose stools but no vomiting, and had slept fairly well. The child had other two loose motions during the day, but not offensive ones like all the other stools. In the evening the child cried—the first time for two days—and as she looked, and was, so much better, I gave her some white of egg with plain, cold, boiled water. Still improving, I kept her on this for three days. She was doing well and I then allowed her milk. She made a complete recovery, and there can be no doubt whatever that Kaylene saved the child's life.

Yours faithfully,

..... M.B., C.M.

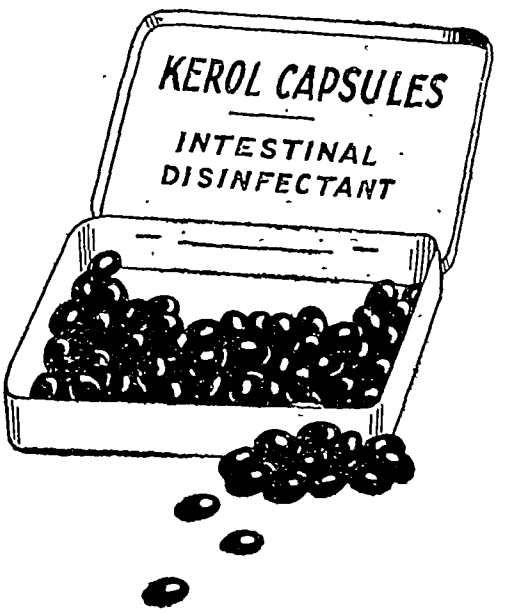
ARTERIO-SCLEROSIS

IT is an old adage that a man is "as old as his arteries," meaning that degenerative changes in the arteries are largely responsible for senility.



The modern view is that arterio-sclerosis is produced by increased blood-pressure, and that increased blood-pressure results from the absorption of "pressor" substances developed by putrefactive bacteria in the intestine.

(Prof. A Robin, among his suggestions for the treatment of arterio-sclerosis, emphasises in the first place the need to remove the alimentary toxic factors which are causative of arterial hypertension.—*Therapeutique Usella du Practicien*, p. 344.)

To retard the activity of the putrefactive bacteria, Metchnikoff introduced the soured milk treatment; but how much better it is to use an antiseptic substance. The ordinary so-called intestinal antiseptics, such as Salol, possess little real disinfectant power, and more potent germicides, such as Phenol, are absorbed, and, in sufficient dose, are toxic.

The active principle of Kerol, besides being a very potent germicide, is not absorbed, and is therefore non-toxic. The rational treatment of arterio-sclerosis would, therefore, include adequate intestinal disinfection by means of the keratin-coated Kerol Capsules.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Vita-Weat—
the perfect "staff of life"

Analysis and tests of Vita-Weat, the British whole-wheat crispbread, show that it possesses in a marked degree the six essential constituents—carbohydrates, fat, proteins, mineral salts, water, *and the essential vitamins.*

100% Whole Wheat.

Being made from the whole wheat berry, from which nothing has been removed in manufacture Vita-Weat yields the highest natural percentage of cereal proteins, and by the process of manufacture the starch present is rendered easily available for the solvent action of the amylolytic ferments of the human digestive juices.

Further, Vita-Weat is specially valuable as a natural stimulant to peristaltic action of the intestines, and when forming a suitable proportion of the daily diet effectively counteracts constipation.

Vitamins A, D and B.

The dry condition of Vita-Weat is of distinct advantage in cases of flatulence in which moist foods are largely contra-indicated, and the crisp character of the sections also helps to reduce the intake of soft foods, giving the teeth and masticating muscles something to do and ensuring complete and thorough salivation of the food bolus.

Vita-Weat crispbread presents the whole wheat berry in a concentrated, attractive and digestible form with the Vitamins A, *D & B in an active condition,* and it forms a valuable addition to rational diet, presenting a dainty and advantageous alternative to soft wholemeal or white bread.

COLLOIDAL ZINC

Native Calamine, which consists of a mixture of Zinc oxide and Zinc carbonate, has been used for a very long time in the treatment of cutaneous disorders. It has some antiseptic action, is slightly astringent and soothing. As ordinarily administered, i.e., as a lotion, the powder, although very fine, will not stay in suspension, with the result that on application a granular deposit appears on the skin which is unpleasant for the patient and apt to soil the clothing. Since the therapeutic action is a surface one only, it also follows that the full therapeutic value of the remedy is not obtained.

COLLOZIN

This is a special Colloidal Zinc Hydroxide which is in every way markedly superior to Calamine Lotion. Collozin spreads better than other zinc preparations, and hence there is a greater percentage of the skin in actual contact with the constituent. It leaves no visible deposit on the skin. It is recommended as a lotion in skin diseases, such as eczema, urticaria, and similar conditions; as a sunburn lotion and as a protective lotion for application to the face prior to exposure to wind, etc.

Collozin is issued in
4 oz., 8 oz., 16 oz., and 80 oz. Bottles.

AN EARLY FORM OF THE MANUSCRIPT WRITING OF THE "ARABIANS." Some of the most prominent men who built up the Arabian Empire were not true Arabs, but Syrians, Greeks, Persians, Copts, Indians and Hispano-Arabians. They achieved a remarkable unanimity, however, in the Arabic language. The ancient learning of Arabia reached the Western world largely through the medium of Arabic translations. Roger Bacon recognised that these were more scholarly than many of the Greek and Latin versions and he counselled the study of Arabic as the best means of acquiring knowledge. But for these translations certain parts of Aristotle and Galen would have been lost to the world.

ON

MASSIVE COLLAPSE OF THE LUNG

(ACTIVE LOBAR COLLAPSE).

DELIVERED TO THE DUNDEE BRANCH ON APRIL 29TH, 1930,

BY

J. M. WOODBURN MORISON, M.D., F.R.C.P.ED.,

RADIOLOGIST TO THE ROYAL INFIRMARY, EDINBURGH

THIS condition has been described under various titles, such as acute massive collapse of the lungs, post-operative massive atelectasis, post-operative pulmonary atelectasis, obstructive massive atelectasis, acute lobar collapse, apneumatosis, and so on.

The title "massive collapse of the lung" was used by Pasteur in his last communication on this subject. It is clear, self-explanatory, avoids the use, as Gairdner puts it, of *sesquipedalia verba*, and covers all deflations of a large area of lung, whatever the cause may be. The condition is found associated with pleural effusions, pneumothorax, bronchial obstructions by growth or foreign bodies, pneumonia, pulmonary tuberculosis, and other inflammatory conditions of the lungs, with certain nerve lesions, and as a complication following surgical operations and injuries. In some of these conditions the lung plays a passive part, but in the post-operative and traumatic cases the lung plays an active part. This was recognized by Pasteur when he used the subtitle "active lobar collapse," and my observations in this paper are limited, more or less, to that type.

ACTIVE LOBAR COLLAPSE

I define this type as an airless condition of the lung, or part of the lung, of sudden onset, lobar in distribution, with coincident accumulation of tenacious mucus in the corresponding bronchi, and accompanied by characteristic physical signs, the chief of which is displacement of the heart towards the affected side.

The condition may be so slight as to pass unnoticed unless specially sought for, or it may be so extreme as to menace the life of the patient. It usually occurs within forty-eight hours of the operation or injury, but cases have been recorded after longer intervals.

In a typical case the onset is sudden, the patient is seized with a sharp pain in the side, has difficulty in breathing, and becomes more or less cyanosed. There is usually a moderate rise of temperature, and it generally precedes the onset. It is rarely above 102° F. There is also an increase in the rate of the pulse and respiration. The tendency is to lie on the affected side or, if pillowed up in bed, to curl up towards the affected side, which on inspection, is seen to be immobilized and retracted, with narrowing of the rib interspaces. Further examination reveals a dullness corresponding to the area of lung collapsed, and over this area there is an absence of breath sounds and tactile vocal fremitus. The heart is displaced towards the affected side, and the apex beat may have shifted two or more inches, in cases where the left lower lobe is collapsed, it is also displaced upwards. Cough is slight and sputum scanty, or they may be absent. There is a compensatory emphysema of the unaffected lung. Later on, these physical signs present great variation, the chest wall is not completely immobilized, the breath sounds become tubular and tactile vocal fremitus is increased. The cough increases, and there is expectoration of tenacious mucus, which, however, is never rusty. As time goes on the expectoration become more copious and less tenacious. Daily variation in the physical signs may occur, auscultation over one area of lung at different times giving quite different results.

The *x* ray examination, an extension of the physical examination by inspection, and in the following cases made in the wards by a portable apparatus, clearly shows

1 The site and extent of the lesion, as evidenced by a dense homogeneous shadow.

2 Displacement of the mediastinum and its contents towards the affected side, the heart shadow being merged with that of the airless lung in the lower half of the hemithorax, this giving an abnormal density. If the right upper lobe alone is affected there may be only displacement of the trachea.

3 Reduction in width of the chest cavity on the affected side with narrowing of the rib interspaces.

4 Elevation and fixation of the leaflet of the diaphragm on the affected side.

5 Pendulum movements of the heart—seen in the later stages when the immobilization of the chest wall is incomplete.

6 Evidence of injury—for example, fractured rib.

7 Compensatory emphysema of the unaffected lung.

The following selected cases illustrate most of these points.

CASE I

Male, aged 19 years. A case of acute appendicitis. Appendectomy at 2 a.m. on January 25th 1923. Anæsthesia—ethyl chloride and ether. Drugs before operation, atropine 1/100 grain after operation, heroin 1/12 grain repeated once.

At 5 p.m. on the same day he complained of a choking sensation, the temperature was 101.4°, pulse 100, and respirations 40. He had pain in the right side and wanted to cough but could not do so. He was cyanosed and had difficulty in breathing. The heart was displaced to the right and the chest wall was fixed on the right side. There was dullness to percussion over the right base, the breath sounds were absent over this area, and vocal fremitus diminished. The *x* ray examination revealed the typical appearances of massive collapse of the lower lobe of the right lung: (1) a dense shadow corresponding to the right lower lobe, (2) displacement of the heart and trachea to the right, (3) narrowing of the rib interspaces on the right side, (4) the line of the diaphragm could not be seen, (5) pendulum movements of the heart were not present, and (6) there was no *x* ray evidence of injury.

There was little alteration in his physical signs during the second day, but he "felt easier." On the third day he was decidedly improving, and the *x* ray examination demonstrated the pendulum movements of the heart. Some movement of the chest wall was taking place on the right side—breath sounds with some crepitations were heard low down over the dull area, and the sounds over other areas were bronchial in type. The temperature fell to 99.2° F. There was some cough and a little sputum. On the fourth day the *x* ray examination showed a continued clearing of the affected lung and less displacement of the heart. On the fifth day a bronchoscope was passed and a quantity of mucopurulent secretion drawn off. He continued to improve, and on the twelfth day the *x* ray appearances were practically normal.

CASE II

A miner aged 21, sustained an injury to his chest while working in the pit. He was taken home and on the following day his doctor, finding that he had a temperature and signs of pneumonia of the left lower lobe, sent him to the infirmary. He was admitted to a medical ward. On admission his temperature was 101° F., pulse 108, and respirations 36. There was dyspnœa and cyanosis. Physical examination marked dullness with increased V.R. and V.F. and bronchial breathing over the lower half of the left hemithorax. These signs varied from day to day. The heart was markedly displaced to the left 2½ inches, the apex beat being also displaced upward. He lay in bed curled up towards the left side, this was his most comfortable position.

The *x* ray examination, on the tenth day of his illness, showed an almost complete obscurity of the lower two-thirds of the left hemithorax, with displacement of the heart and trachea to left. The contour of the left leaflet of the diaphragm was visible. On the right side there were fractures of the fourth, ninth, and tenth ribs.

The sputum was scanty, tough and tenacious, but never purulent. He slowly improved, the highest temperature was 101.4°. It reached normal on the ninth day, but it was not until the twentieth day that the *x* ray appearances were normal.

This was a post-traumatic contralateral massive collapse of the lung.

and lower lobes of the right lung, with displacement to the collapsed side of the heart and trachea. The narrowing of the rib interspaces was also well shown.

Progress was uneventful. By the eighth day after the operation the temperature had reached normal, and on the sixteenth day the chest presented normal radiographic appearances.

CASE IV.

Female, aged 15 years. Appendicitis—appendicectomy—no complication. Anaesthetic: ethyl chloride and ether. Drugs: before operation, atropine 1/100 grain; after operation, heroin 1/12 grain, repeated once.

Six days after the operation this patient had a sharp pain in the left side of the chest and some dyspnoea. The temperature was 97.6°. Physical examination: marked dullness over lower half of left chest, V.R. and V.F. increased. Movements of left chest diminished. Heart displaced to the left. On the following day she was much better, having coughed up some thick tenacious sputum.

The *x*-ray examination was not made until two days after the onset of chest symptoms. It showed some obscurity of the lower lobe of the left lung, with displacement of the heart to the same side. Pendulum movements of the heart during respiration were noted. Five days later the chest presented normal *x*-ray appearances. The temperature never rose above 99° F.

CASE V.

Female, aged 9 years. This little girl's illness began suddenly on the morning before admission to the medical wards. She woke with a headache, felt shivery, and vomited once. During the day she coughed more than usual, for she had been troubled by a recurring cough for some years, and complained of pain in the left side. In the evening she became delirious. Next day the doctor sent her into hospital.

On admission her temperature was 102.6° F., respirations 40, pulse 154; the sputum was scanty, greenish, not rusty, and contained Group IV pneumococci. Physical examination: left lung dull all over, but especially inferiorly, where the breath sounds were hardly audible; elsewhere breathing was audible, and posteriorly about the middle was bronchial in character.

There was a tendency for the temperature to settle by lysis, and on the ninth day of her illness it had fallen to 97° F.; on the tenth day it rose to 100.6° F., and on the following day to 102° F., after which it became subnormal, ranging from 96° to 98° F. during the rest of her illness. It was not until the twelfth day that an *x*-ray examination was made, and it revealed almost complete obscurity of the left hemithorax, with displacement of the heart and trachea to the same side. There was no elevation of the diaphragm on the left side, but it was fixed.

The *x*-ray examination was repeated from time to time, and the gradual return to the normal watched—about twenty-eight days after the onset of her illness. Fifteen days later, however, while still in hospital, a further *x*-ray examination revealed a patch of consolidation in the middle lobe of the right lung, which cleared up in the course of a few days. There was no rise of temperature, nor did she seem in any way affected by it. A week later the chest was apparently normal, and she went home in good health.

CASE VI.

Female, aged 13 years. Appendicectomy, no complications. Anaesthetic: mixture and ether. Drugs: before operation, atropine 1/100 grain; after operation, heroin 1/24 grain, repeated once.

On the day following the operation she developed a cough and brought up small quantities of muco-purulent sputum. There were numerous rhonchi over both lungs—most marked at the right apex. Both lungs were equally resonant to percussion. On the third day after the operation (about forty-eight hours) the temperature rose to 102° F. She was very breathless; pulse was 140 and respirations 120.

Physical examination: Areas of patchy dullness alternating with areas of normal resonance over the right lung—tubular breathing and whispering pectoriloquy noted. Later there was dullness over the whole of the right lung and almost complete suppression of breath sounds. The heart was displaced to the right side.

The *x*-ray examination showed complete obscurity of the right hemithorax, with displacement of the heart and trachea to the same side. The condition quickly cleared up, and by the fifteenth day was apparently normal.

CASE VII.

Male, aged 32. Acute gangrenous and perforated appendix. Appendicectomy and drainage. Anaesthetic: ethyl chloride and ether. Drugs: before operation, atropine 1/100 grain; after operation, heroin 1/12 grain.

On the evening of the sixth day after the operation the temperature rose to 102° F. There was slight dyspnoea and cyanosis—dullness at the left base and tubular breathing over this area. The heart was displaced to the left, the apex beat being well outside the nipple line. The following morning the whole condition had practically cleared up, and the *x*-ray examination showed a little obscurity at the base of the left lung. He made an uninterrupted recovery.

CASE VIII.

Male, aged 8 years. Operation for repair of ventral hernia. Anaesthetic: ethyl chloride and ether. Drugs: before operation, atropine 1/100 grain; after operation, heroin 1/12 grain, repeated once.

On the day following the operation he developed chest symptoms. There was dullness and diminished breath sounds at the left base; the heart was displaced to the left, the apex beat half an inch outside the nipple line. There was marked cyanosis and breathlessness. The *x*-ray examination on the fourth day showed a typical massive collapse of the lower lobe of the left lung; the temperature had risen to 103° F. By the fourteenth day he had made a complete recovery, and I think was greatly benefited by the administration of CO_2.

COMMENTARY.

These cases illustrate the post-operative type, the post-traumatic type, and a type found in Case v which, I think, must be said to be associated with a pneumonic condition of the lung. They also illustrate the varying degrees of severity of the condition, so slight that it might easily have passed unnoticed, in others so severe as to cause doubts regarding the recovery of the patient. It will also be noted that in the post-operative cases the anaesthetic used was ether and that atropine was given before the operation, followed by heroin after the operation. In Case viii morphine was also given. In Cases ii and v no anaesthetic and no drugs of the nature of heroin and morphine had been administered. Most of the cases I have seen have occurred in young people, and the condition is a common accompaniment of lobar pneumonia in children. Cases have been recorded by Sewall associated with pulmonary tuberculosis, and Jacobaeus records similar cases; Jacobaeus also described its occurrence associated with pneumonia and with lipiodol injections of the bronchi. Others have recorded cases as occurring after slight injury, severe injury, and during infective processes. Regan records a case associated with acute poliomyelitis. The more one hunts for this condition, the oftener one finds it, and I cannot help feeling that Bowen is right in emphasizing the teaching of Sewall to "think atelectasis" when engaged in any phase of lung examination.

At this point it is necessary to differentiate clearly the condition under discussion—active lobar collapse—from massive collapse of the lung in cases of pleural effusion, pneumothorax, and bronchial obstruction by growth or foreign body. In these cases the collapse is comparatively a gradual process and the symptoms are rarely of a distressing character. Even in spontaneous pneumothorax the initial distress quickly passes off, and in complete obstruction by a foreign body the bronchus soon becomes *tolerant*, the collapse of the area of the lung supplied taking place slowly as the air is absorbed by the blood stream. In this process the lung plays a passive part. The density of the collapsed lung in these cases, if the collapse is complete, is just as great as it is in active lobar collapse. In a bronchial carcinoma it is impossible to separate out the shadow of the tumour from that of the collapsed lung, yet at the post-mortem examination the tumour was of relatively small size. Sante states that "the transparent structure of the lung collapsed in pneumothorax is difficult to understand and has never been successfully explained"; but in pneumothorax it is rare to find a completely collapsed lung. There is usually some air present, and if a portion of the lung is completely collapsed it gives a shadow just as dense as in active massive collapse. The conditions which Sante describes are not analogous. In the one air fills the pleural cavity and exerts an elastic pressure on the lung, seldom causing complete pulmonary collapse; in the other there is a complete deflation of the lung with a falling in of the ribs, elevation of the diaphragm, and displacement of the mediastinal contents to compensate for the space lost.

The name of William Pasteur of Middlesex Hospital must ever be associated with active lobar collapse, a clinical entity first clearly described him.

In 1890, writing on "Respiratory paralysis after diphtheria as a cause of pulmonary complications," he records his observations on fifteen cases of diphtheritic paralysis in which the muscles of ordinary respiration, especially the diaphragm, become more or less involved, with evidence of disturbed function of the lungs—"In other words there was evidence in the majority of cases of imperfect entrance of air into, and of some oedema of, the hinder parts of the lungs, more especially towards the bases, with condensation or consolidation of the organs in several of them."

In all these cases, with the exception of one, the condition was more or less bilateral. Regarding that one (Case vi) he writes: "I have little or no hesitation in attributing the physical signs to wholesale collapse of the right lung induced by the immobility of the right half of the chest, and the paralysis of the diaphragm."

In 1903 he delivered the Bradshaw Lecture, on the subject of massive collapse of the lung, using the term "massive" for the first time. In this lecture he refers to 64 cases of diphtheritic paralysis, in 28 of which the diaphragm was affected; 15 died, 12 recovered, and 1 was lost sight of. There were eight post-mortem examinations, and these revealed varying conditions from small patches of collapse on the posterior parts of both lungs to collapse of a whole lobe; in some of the cases a broncho-pneumonic condition with patchy areas of collapse in both lungs was recorded. He describes four cases of massive collapse of the lung found in the post-mortem room, one following laparotomy, the other three being medical cases associated with: (1) chronic ulcer of the stomach; (2) liver abscess; (3) hydrochloric acid poisoning with extensive damage to the oesophagus, stomach, and duodenum. He thinks that the extent and degree of collapse is as great in these cases as in those due to paralysis of the diaphragm, regarding it as caused by intense reflex inhibition of movements of respiration of sufficient intensity and duration to cause massive collapse of the lung, and suggests that some cases diagnosed as post-operative pneumonia are really massive collapse. He differentiates massive collapse, an active process in which the elastic property of the lung plays its part, from lobular collapse, a passive process of removal of air after plugging of a bronchus.

In 1910 he wrote on active lobar collapse of the lung after abdominal operations, and here is found the first full and complete account of the post-operative condition with its cardinal sign of cardiac displacement.

In 1914 his final paper was published under the title "Massive collapse of the lung" (*syn.* active lobar collapse). It is a clear statement of his work on this subject from the post-diphtheritic cases of 1890 to the post-operative cases which he correlated with them. He defines the condition as a

"total deflation (as opposed to lobular or patchy collapse) of a large area of lung tissue, of sudden onset—in the absence of any signs of obstruction of the airway or of any known cause of obstruction—due to failure of inspiratory power and attended by definite physical signs and symptoms."

He recognized two well-defined varieties: (1) cases in which the lesion is demonstrably due to paralysis of some of the essential muscles of respiration (diaphragm—intercostals); the collapse is usually bilateral; (2) cases in which collapse supervenes suddenly, without any premonitory signs of respiratory paralysis, and in which the lesion is apparently always unilateral.

He regarded failure of respiratory power as the essential cause of massive collapse, and post-operative collapse as being the result of (reflex) arrest of action of one-half of the diaphragm.

If Pasteur's definition of this condition be accepted so must also his theory, as the definition includes the theory, and it is for this reason that I, at the beginning of this paper, submitted another definition. Pasteur's theory might be called the theory of failure of inspiratory power, the lung playing an active part.

I have dealt somewhat fully with Pasteur's writings, first, because they are a striking example of a brilliant clinical investigation extending over a large number of years, in which the development of the author's ideas can be traced from the post-diphtheritic cases up to his classical description of the post-operative condition; secondly, because he is so often misquoted, and writers forget that he definitely regarded the lung as playing an active part, so much so that he uses as a synonym the title "active lobar collapse," although, in my opinion, he did not stress sufficiently the active part played by the lung.

In 1914, following Pasteur's paper, Elliott and Dingley published eleven cases; all followed abdominal operations—appendix, gall-bladder, gastro-enterostomy, and hernia. They admit that the bronchial muscles are strong enough to cut off the air entry to the alveoli, but think it most unlikely that they would be excited to such a reflex action locally and cause lobar collapse, nor would the condition be established without a preceding phase of asthma. They advance the theory that the cause is the absorption of air where the bronchioles are obstructed owing to inflammatory oedema and secretion, stating that in all their cases there was the possibility of such local obstruction, for every patient had muco-purulent expectoration before or immediately after the onset of the collapse.

They failed to induce collapse in animals by: (1) division of the phrenic nerve on one side; (2) hemisection of the spinal cord at the second and third cervical segments—paralysis of the intercostals and diaphragm on one side.

In 1918 Crymble recorded fifteen cases following gunshot wounds, and suggested that the contralateral cases were due to the patient lying on that side.

In 1920 Rose Bradford, writing on this subject, stated that while it seemed incredible the evidence would seem to indicate that a reflex spasm of the bronchioles was the cause of the obstruction.

Charlton Briscoe in 1920 analysed the possible causes of massive collapse, and concluded that it was produced

"by the onset of inflammation affecting the muscles of the crus situated behind the peritoneum, one half of the diaphragm and its synergistic and antagonistic muscles are out of action owing to inflammation of the muscle or the pleural membrane covering it."

In 1921 Sewall of Denver drew attention to the frequency of atelectasis in cases of pulmonary tuberculosis, and this has recently been emphasized by Jacobaeus.

In 1924 Regan reported a case following poliomyelitis.

In 1925 Jackson and Lee analysed the diverse condition under which massive pulmonary collapse occurs, and showed two factors to be practically constant: (1) obstruction of the bronchial tree, followed by absorption by the pulmonary circulation of the air imprisoned in the alveolar air spaces distal to the obstruction; (2) some interference with respiratory movements—partial or complete—but always resulting in decreased aeration of the pulmonary tissue on the involved side.

Later in the same paper they speak of two of the factors underlying pulmonary collapse, either massive or partial—namely, inhibition or arrest of respiratory movements, and subsequent obstruction of the bronchi with accumulated bronchial secretion.

In 1927 Sante reported three unusual cases, one of which was bilateral; and another bilateral case was reported in the same year by Bergamini and Shephard. Sante concludes that

"the cause is not known, but it seems most probable that some infection or insult to the region of vagus supply produces a reflex action on the bronchioles, permitting their temporary collapse. Once approximated the walls of these bronchioles are held in apposition by adhesion, collapse of the lung rapidly following owing to absorption of the alveolar air by the circulating blood. Relief of the obstruction results in sudden re-inflation of the lung."

Mastics, Spittler, and McNamee write of it as a common post-operative complication, and regard the majority of post-operative pneumonias, bronchitis, and broncho-pneumonia as cases of atelectasis.

Scott and Joelson think the original cause is not yet proven, but regard the fundamental condition which initiates massive collapse as being a nervous reflex which affects both lungs and commonly occurs in a minor degree. They suggest that the posture of the patient determines the localization of the condition. This had been suggested previously by Crymble.

In 1928 Corylios and Birnbaum came to the conclusion, from both the experimental and clinical work done by them, that the only cause is the complete occlusion of a bronchus by a plug of mucus acting as a foreign body, the other causes being predisposing factors.

In the present year they have published the results of further research work, and advance the mucus plug theory to explain not only massive collapse of the lung, but also pneumonia. They assert that in pneumonia it is the blocking of the lung air passages, bronchi, or bronchioles by plugs of thick sticky secretion which is the critical pathological factor. They regard massive lobar collapse as the condition from which post-operative pneumonia develops. They advocate the treatment of pneumonia, and, of course, of massive collapse by the inhalation of an oxygen mixture containing 5 per cent. carbon dioxide, and report several hundreds of cases treated in this way with excellent results.

In 1929 Bowen of Philadelphia published his admirable monograph on acute massive collapse. He deals with the subject in all its phases, and gives an exhaustive account of the literature with 220 references. He supports the theory of bronchial obstruction and advocates "bronchoscopic drainage, skilfully done" as an important method of treatment.

From the foregoing it is obvious that there are four main theories as to the cause of this collapse:

1. The theory of failure of respiratory power, the lung playing an active part. (Pasteur.)

2. The mucus plug theory. (Elliott and Dingley, Jackson and Lee, Coryllos and Birnbaum, Bowen, and many others.)

3. Reflex spasm of the muscles of the bronchioles. (Rose Bradford, Sante, and others.)

4. Inflammation of the crus and one half of the diaphragm or the pleural membrane covering it. (Charlton Briscoe.)

Pasteur's contention that the condition is brought about by paralysis of the diaphragm and other respiratory muscles explains the cases, which he first described, of respiratory paralysis after diphtheria in which he found an airless condition of the lower lobes of the lungs with some oedema, but it does not account for the massive collapse which we are discussing, in which the leaflet of the diaphragm is raised and fixed, but not paralysed. It is fixed in the expiratory position, which is the position of rest. A complete paralysis of one leaflet of the diaphragm is not followed by collapse of the lung, and Elliott and Dingley were unable experimentally to produce collapse by division of the phrenic nerve or hemisection of the spinal cord at the second and third cervical segments.

Briscoe's theory of retroperitoneal infection of the crus also fails, as too many cases have been recorded where there was no possibility of this taking place.

The theory of bronchial obstruction by mucus plugs is a very old one.

Gairdner in 1850 advanced his well-known ball valve theory to account for lobular collapse of the lung, and ridiculed the theory of Fuchs that the air imprisoned in the alveoli behind the obstruction was either received into the circulating blood or in some other way absorbed, as gaseous substances are when they are extravasated into the cellular tissue. He quotes the experiments of Mendelssohn and Traube, who introduced "leaden shot," balls of paper, and gum into bronchi in the dog, producing collapse of the corresponding portion of lung. He quotes the experiments of Reid, Longet, Shiff, and others on the effects of sections of the pneumogastric trunk, or of its visceral branches, on the lungs and bronchi. These experiments concurred in proving that these operations are followed by a very large accumulation of frothy mucus in the bronchi. The lung changes were imperfectly described. At the present day Gairdner's ball valve theory has been displaced by that of Fuchs's, which is ridiculed.

Lichtheim proved experimentally that areas of lung tissue distal to a plugged bronchus became atelectatic, if the circulation were not interfered with, but that no collapse occurred if the blood vessels to that part were tied.

Elliott and Dingley were the first of the modern writers to advance the theory of bronchial obstruction due to inflammatory oedema and secretion, and they have been followed by Jackson and Lee, Coryllos and Birnbaum, Bowen, and many others.

Now the accumulation of mucus in the bronchi is a slow process, the mucus becoming gradually tough and tenacious, and the absorption of air imprisoned in alveoli behind the obstruction is a slow process—the nitrogen is not readily absorbed; but the onset of massive collapse is sudden, often dramatically so.

The advocates of the mucus plug theory have to explain, first, why the mucus accumulates; secondly, why in a particular situation; and, thirdly, the formation of a plug large enough to cause a bilateral collapse, for such cases have been recorded.

The post-mortem examinations recorded by Pasteur and Rose Bradford did not reveal any gross bronchial obstruction such as would cause the collapse, and Rose Bradford further states that there is often no clinical evidence of bronchial obstruction.

The mucus theory by itself is untenable, but Jackson and Lee were careful to postulate two factors—namely, inhibition or arrest of respiratory movements, and subsequent obstruction of the bronchi with accumulated bronchial secretion.

The posture which patients tend to assume after certain operations or injuries would provide this inhibition or arrest of respiratory movements, and there is no doubt that experimentally the condition can be induced. This was accomplished by Mendelssohn and Traube in 1845–46, and in our own time by Coryllos and Birnbaum, and by Lee, Ravdin, Tucker, and Pendergrass. These latter introduced into the bronchus of a dog a mucus plug removed from a man by the bronchoscope. Gum arabic solution was also used by them. They found that they could produce a typical collapse if they inhibited the cough reflex. There is thus no doubt that, experimentally, mucus, *plus* the inhibition of the respiratory function, will cause a collapse of the lung in dogs; but does this occur in active lobar collapse as we know it in man?

In many cases there is no question of inhibition of respiratory function by posture. One case recorded by Rose Bradford occurred as the result of a gunshot wound. No anaesthetic had been given. The wound was so slight that the patient had not been confined to bed prior to the onset of the collapse. There were many cases investigated by the same writer in which neither the clinical examination nor the post-mortem examination lent any support to the mucus plug theory. He further states that in these cases, seen during the war, the essential factor in the etiology was the wound, and that the condition might ensue in its most marked form, where other supposed factors, such as anaesthesia, posture, injury to the diaphragm or its nerves, exudates, secretion, or blood in the bronchial tubes, could be excluded. He was driven to the conclusion that the cause was a reflex stimulation of constrictor nerve fibres to the muscles of the bronchioles or some such process leading to their occlusion. In this view he is strongly supported by Sante, who states that

> "all cases reported have followed either some toxic condition, such as diphtheria, poliomyelitis, streptococcus septicaemia, or some insult to the nervous supply of the vagus; abdominal or chest injuries or operations. Any one of these conditions could serve as the necessary reflex stimulus to the constrictor fibres of the bronchioles."

The post-mortem examinations are few, for nearly all the cases fortunately recover. Ritvo states that

> "the involved portion of the lung is blue or violet in colour, and sharply demarcated from the normal lung tissue. It is soft, tough and wet; it feels heavy, does not crepitate, and sinks when placed in water. Microscopically the alveolar surfaces are closely approximated, the alveolar spaces being obliterated."

Any theory to be sustained must account for: (1) the accumulation of mucus in the bronchial tubes; (2) the rise of temperature often before the collapse occurs, or no rise of temperature; (3) the sudden onset of the major symptoms—often dramatically so; (4) the varying time after operations or injury of the sudden onset; (5) the occurrence of cases apart from anaesthetics, operations, or serious injury; (6) the occurrence of cases as a complication of inflammatory diseases in the lungs; (7) the contralateral cases; (8) the bilateral cases.

Any one of the theories previously mentioned can account for some of the cases, but none of them can account for all of them.

It is only when the lung is considered as a "muscular organ," to use Macklin's term, playing an active part, that the mechanism of the collapse is fully explained.

As far back as 1822 Reisseisen traced the muscle coat, by dissections done with a hand lens, down to the finer bronchioles, and inferred that it continued to the ends of the air tract. Baltisberger states that there is hardly a cubic millimetre of lung tissue which does not contain smooth muscle, and Macklin's work shows that the lungs are muscular organs in a very real sense. This has become increasingly obvious in recent years, the musculature being of great functional importance and indispensable in respiration.

The bronchial musculature can be regarded as a contractile net embracing the mucosa of the entire bronchial tree from the larynx to the alveolar mouths. Intermingled with the muscle coat is a loosely woven layer of elastic fibres, the whole being described by Macklin as "myo-elastic tissue," the elastic property ensuring evenness of action.

During inspiration the musculature is in a state ready for dilatation, and this dilatation is associated with lengthening and separation of the bronchi, the angles becoming smaller. The inspiratory act is passive so far as the lung is concerned, active as regards the chest wall and

the diaphragm. It is during expiration, which is a passive movement in the external muscles, an active movement in the lungs and bronchial tree, that the lung plays an active part; shortening and narrowing of the bronchial tubes takes place, the angles becoming wider. It is in all probability a wave-like motion, resembling peristalsis, travelling from the terminal bronchioles upwards. This movement was suggested by Gairdner, who in 1850 described it as the deobstruent action of the bronchial tubes. It is one of the factors in the movement of mucus upwards in the bronchial tubes.

That spasm does occur in the lung is evident in cases of asthma, and recently Jacobaeus has found that, in lipiodol injections of normal bronchi, massive collapse does occur. In hundreds of pathological cases in which lipiodol injections into the bronchi were made he never came across any massive collapse, but in cases where the bronchi were normal he found it of common occurrence. It was not the quantity of lipiodol, which was in some cases relatively little and could not possibly have caused complete occlusion of the bronchi, which caused the condition, and he could only explain the phenomenon as due to some contraction or spasm of the bronchi. The capacity for contraction or spasm in pathologically changed bronchi is greatly reduced.

There is no doubt that in many inflammatory diseases of the chest massive collapse is found, and the more one looks for it the more frequently one finds it. It has been found in pneumonia and in pulmonary tuberculosis, and it is an accompaniment of lobar pneumonia in childhood. Out of eight cases of lobar pneumonia recently investigated in young children, six presented the cardinal signs of massive collapse, and I have come to the conclusion that, while it is a common accompaniment of lobar pneumonia in children, it is not uncommon in young adults.

I am of opinion that the primary cause of active collapse of the lung is a reflex disturbance of the sympathetic and vagus innervation of the lungs, resulting first in a dilatation of the bronchi with cessation of the wave-like movement and a consequent accumulation of mucus. This I regard as due to an overacting sympathetic, and it is at this stage that the slight rise of temperature so often occurs. The balance between the sympathetic and vagus may be quickly restored and the condition rapidly clear up with the return of cough and the expectoration of mucus. On the other hand, as the overaction of the sympathetic passes off, the vagus may reassert itself too strongly and cause a sudden spasm of the musculature involving a whole lung or a lobe of the lung, or even, in rare cases, both lungs, for the lung is a muscular organ.

It is not necessary to conceive of the spasm persisting any great length of time for the condition to be established; it not only empties the lung tissue more or less of its air content, but when the walls of the alveoli and terminal bronchioles are brought into apposition, the molecular adhesion effectively prevents the re-entry of air. This accounts for the sudden onset and the varying time after operation or injury at which it occurs.

The chest wall and diaphragm accommodate themselves as far as they can to the altered conditions in the chest, but they cannot fully compensate for the smaller space occupied by the lung, consequently the mediastinal contents are drawn over to the affected side, the chief physical sign being displacement of the heart. It is during this stage that the patient has pain in the side and is cyanotic. As he becomes accustomed to the sudden alteration in the chest conditions the pain passes off, sometimes in a few hours; the cyanosis is of varying duration and persists until there is sufficient diversion of the blood to the sound lung to ensure adequate aeration.

Fortunately, the termination of these cases is almost always favourable. If untreated one finds in the course of a day or two that the patient is coughing up mucus, which, however, is never rusty; in other words, the wave-like movement of the bronchial tubes is at work again: the balance between the vagus and sympathetic has been restored. Gradually air re-enters the alveoli, never all at once, unless some powerful force has been applied as in forcible compression of the chest with sudden relaxation which causes the ribs to spring out, and in some cases induces the entry of air in much the same way as the first entry of air to the lungs in the newborn.

I agree that there are many predisposing causes, such as drugs which inhibit the cough reflex, post-operative postures which interfere with the free movement of the chest wall and diaphragm, and any condition in the lung itself which interferes with the nervous mechanism of its musculature, but the primary cause is a sympathetic and vagal disturbance.

Yet one question remains. *Is there any analogous condition which might throw light on this subject?* I think there is. Acute dilatation of the stomach is recorded as occurring under very similar conditions, accompanying or following operative procedures or associated with traumatism. Post-diphtheritic cases and cases associated with multiple peripheral neuritis have also been recorded. The onset is sudden, often dramatically so, and the gastric dilatation must be regarded as a primary, not a secondary, phenomenon. There is a sympathetic nerve disturbance, and in many ways massive collapse of the lung and acute dilatation of the stomach may be regarded as analogous conditions.

I feel sure that, in the examination of the chest, the more one keeps in mind the possibility of active lobar collapse the oftener it will be found, more especially in children and young adults.

SUMMARY.

1. Collapse of the lung, lobular and diffuse, was well known to the clinicians from the time of Laennec onwards, but William Pasteur was the first to give a clear account of the condition known as massive collapse of the lung (*syn.* active lobar collapse).

2. Active lobar collapse must be clearly differentiated from massive collapse of the lung of a passive character.

3. The function of the musculature of the bronchial tubes may be deranged by various causes acting on the sympathetic and vagal innervation either directly or reflexly.

4. The weight of evidence is in favour of the theory that spasm of the bronchial musculature is the essential feature of active lobar collapse, but the disturbance of the sympathetic innervation must also be taken into account.

5. In the examination of the chest the more one keeps in mind the possibility of active lobar collapse, the oftener it will be found, more especially in children and young adults.

Dr. Geraghty revealed small bilateral basal pleural effusions. There was achlorhydria and a mild secondary anaemia. The patient was on a low protein diet for about a month previous to admission.

Function Tests and Blood Chemistry.

The total protein, albumin, and globulin determinations were performed on plasma, by the combined methods of Howe,[9] Wu,[10] and Kock and McMeekin,[11] as described by Hawke and Bergeim[2], blood cholesterol was estimated as described by Myers and Wardell,[13] blood phosphorus by the method of Benedict and Theis,[14] and blood calcium by the method of Clark and Collip.[15] The Roth-Benedict portable spirometer was used for estimating the basal metabolic rate.

The phenolsulphonephthalein excretion test gave a figure of 60 per cent. in two hours, 600 c.cm. of urine was excreted in four hours after ingesting 1,000 c.cm. of water. The fixation test of the urine showed no inability of the kidney to concentrate. The following blood values per 100 c.cm. were obtained shortly after admission.

Urea 28 mg., uric acid, 2·5 mg., creatinin, 1·4 mg., non protein nitrogen, 30 mg., cholesterol 600 mg. (normal about 180), calcium 8·9 mg., and phosphorus, 1·4 mg. The plasma chloride content was 456 mg.

The basal metabolic rate was −12 per cent. at a period when the oedema was slight, and apparently confined to the shins and ankles. The differential blood count was normal. The urea concentration test gave 2·12 per cent. of urea in the first hour and 2·53 per cent. in the second. The blood serum was milky. The total amount of albumin excreted in twenty four hours was 4·8 grams. On admission there was oliguria (about 800 c.cm. in the twenty-four hours) but later the urine volume became about normal in amount, in correspondence with the fluid intake.

The erythrocytes numbered 4,000,000 and the leucocytes 6,000 per c.mm. The haemoglobin percentage was 60. The blood Wassermann reaction was negative.

Blood Protein Determinations.
(Grams per 100 c.cm.)

	Jan. 2	Jan. 8	Jan. 20	Mar. 12	April 7	Normal Figure
Total protein	2·5	2·2	2·3	5·58	5·8	6·5 to 8·2
Albumin .	1	2·1	2·5	3·7	3·1	4·6 to 6·7
Globulin ..	1·4	0·7	0·35	0·18	2·6	1·2 to 2·3

This table indicates that the case before treatment showed reversal of the normal albumin globulin ratio, and marked diminution of the total protein. Double refractive lipoid globules were found in abundance free in the urine, in the casts, and in desquamated renal epithelium by Dr. R. A. Q. O'Meara (see Part II). The retinal arteries showed a slightly increased light reflex, and there was evidence of compression of the retinal veins under the arterial crossings (beginning arterio-sclerotic changes), these findings were confirmed by Dr. D. O'Donoghue, assistant ophthalmologist to the hospital.

It is interesting to note that after a profuse diuresis induced by ammonium chloride and salvigan, the oedema practically disappeared, the blood pressure fell to 144/94, and the basal metabolic rate was −5 per cent.

Treatment.—The diet consisted of 120 to 140 grams of protein, about 60 grams of fat, unlimited carbohydrate, moderate restriction of salt, and about 1,200 c.cm. of fluid per day. Thyroxine was given for a few days, dilute hydrochloric acid and iron were administered. Periods of a few days on ammonium chloride were followed by a few single intramuscular doses (2 c.cm.) of salvigan to control the oedema, and there were occasional exhibitions of digitalis. The duration of observation was about five months. The patient was only confined to bed for the first few days, and thereafter was allowed exercise in moderation.

Result.—Great improvement in the general health ensued with disappearance of anaemia and of the pleural effusions, lowering of the blood cholesterol from 600 to 270 mg. per 100 c.cm., increase of the serum proteins as shown in the table, and lowering of the body weight from 151½ lb. to 124½ lb., due apparently to almost complete disappearance of the oedema and the pleural effusions. The blood pressure on discharge was at about the same level as on admission, the fall after the previously mentioned diuresis being transitory.

The patient is probably beginning to develop arterio-sclerotic changes, as is evidenced by the elevation of the blood pressure and the slight changes in the retinal arteries; this may possibly be due to involvement of the glomeruli in the pathological kidney process. The case is interpreted as being one of impure lipoid nephrosis.

It is a pleasure to acknowledge the efficient assistance of Dr. K. Malley, the house-physician, and Mr. M. Moriarty, M.Sc., the resident student, in the study of this case.

PART II.—PATHOLOGICAL.

BY

R. A. Q. O'MEARA, M.B., M.Sc.,

ROCKEFELLER FOUNDATION FELLOW IN TRINITY COLLEGE, DUBLIN.

LIPOIDURIA is an almost constant finding in lipoid nephrosis. It was regarded by Munk[5] as pathognomonic of the condition. This view, however, has been challenged since lipoids, similar in characteristics to those found in the urine in lipoid nephrosis, are found in other conditions as well. Not only do they occur in the urine in different types of renal disease, but also in certain chronic intoxications and metabolic disorders associated with increased blood cholesterol, such as diabetes. In lipoid nephrosis, however, they are usually present in abundance.

When seen with the ordinary microscope in a urinary deposit from a case of nephrosis they appear as fatty globules either free in the casts or in renal epithelium. The polarizing microscope, however, reveals the fact that many of the lipoid globules possess exceptional properties. When viewed with the aid of this instrument, the Nicol prism being crossed, many of them are seen to present a remarkable appearance, showing up brightly as Maltese crosses of light against the dark field. While the Maltese cross is the predominant pattern, other less striking patterns are also to be seen. One of these resembles a cross of light the centre of which has been blacked out, another a ring of light encircling a dark centre.

The physical properties of the globules which are responsible for these appearances, are summed up in the adjective anisotropic, by virtue of their anisotropism they are doubly refractive. In a sense they are unique, since anisotropism is a property of crystalline solids. The globules, however, are fluid, and their discoverer O. Lehmann has called their physical condition the liquid crystalline state of matter. Chemically they are esters of cholesterol, but not in the pure state, since esters of cholesterol alone are not doubly refractive. The work of Aschoff, Windaus, and others shows that they are admixed with free fatty acids, fats, or phosphatides.

In the urinary sediment from Professor Moore's case, anisotropic lipoids were present in profusion and were well demonstrated in photographs taken with the polarizing microscope. One of these photographs showed a cast in which the crosses of light, large and small, are apparent. In the neighbourhood of the cast could be distinguished the shadowy forms of renal cells which likewise contained anisotropic globules, other globules were free.

What is the pathology of the condition which gives rise to these bodies in the urine in lipoid nephrosis? Is the condition primarily a metabolic disease with secondary involvement of the kidney, or is it primarily a disease of the kidney from which the other phenomena of the condition follow? An extensive critical review of the literature of the condition, combined with personal study of a number of cases was given recently by Bell[16] who discusses in detail the clinical features of the disease and the post-mortem appearances in cases which terminated fatally. Using a modification of Mallory's aniline blue connective tissue stain, he has been able to demonstrate that the endothelial cells of the glomeruli of the kidneys are increased in both number and size, and that there is an addition of cells in both number and size, and that there is an addition of cells in both number and size, and that there is an addition of cells

occur nor does contraction commonly set in as a later event. In the usual form of glomerulo-nephritis, on the other hand, the degree of capillary blockage is much greater, leading to functionless hyaline glomeruli, atrophied tubules, contraction of the kidneys, and to uraemia. Lipoid nephrosis does not terminate in uraemia. In cases which do not recover, death is most commonly due to peritonitis, pneumonia, or septicaemia. The frequency of peritonitis is remarkable, as it accounts for almost half the deaths; where the responsible organism has been isolated it has been found to be pneumococcus.

There can be little doubt that the lipoid which is deposited in the renal cells, and which finds its way thence into the urine, is an outcome of the very high cholesterol content of the blood. Its constant deposition in the convoluted tubules, and to a lesser extent in the glomerular cells, suggests that an endeavour is being made to excrete the surplus. As to the cause of the cholesterolaemia we have no certain knowledge; it may be secondary to the great loss of albumin in the urine sustained by sufferers from this form of renal disease. As in diabetes, so in lipoid nephrosis, mobilization of fat from the reserves may occur in an attempt on the part of the system to feed tissues partially starved by the constant drainage from the body, in the one case of carbohydrate, in the other of protein. Of the fat so mobilized, the cholesterol fraction is stable and relatively valueless as a source of energy. It seems possible that this fraction is taken up by the renal cells, and in particular by the cells of the convoluted tubules, where it is deposited, some eventually passing away in the urine either by disruption or shedding of the cells. This process of excretion of cholesterol is analogous to a physiological process by which an isomer of cholesterol is excreted in the normal individual: the secretion of the sebaceous gland involves a degenerative process in which isocholesterol is first laid down in the gland cells, and later, either by disruption of the cells or by their separation from the gland, is discharged and lubricates the skin and its appendages.

Finally, as to the cause of lipoid nephrosis: in view of the probability that it is in reality a chronic mild glomerulitis, one should bear in mind that two bacterial toxins are definitely known to select the glomerulus of the kidney for attack. They are the toxins of the diphtheria bacillus and of the haemolytic streptococcus. The cause of lipoid nephrosis is unknown, but there is justification for suspecting a bacterial origin. One organism, the pneumococcus, suggests itself for study. Why is it that so many of the patients die of pneumococcal peritonitis?

INSOLUBLE PRECIPITATES IN DIPHTHERIA AND TETANUS IMMUNIZATION.

BY

A. T. GLENNY, B.Sc.,

WELLCOME PHYSIOLOGICAL RESEARCH LABORATORIES, BECKENHAM, KENT.

THE addition of aluminium sulphate or potash alum to a diphtheria toxoid produces a relatively insoluble precipitate which has high antigenic properties. Glenny, Pope, Waddington, and Wallace (1926), and Glenny and Waddington (1928), have shown that such precipitated toxoid immunizes guinea-pigs more readily than the original toxoid.

In view of the promising results obtained,* it is possible that the most favoured method of human immunization against diphtheria in the near future may be by means of a suspension of toxoid precipitated by alum; it appears to be of interest, therefore, to present some results of animal experiments with both diphtheria and tetanus toxoid showing the extent to which the antigenic efficiency is increased by the addition of alum. During the course of our experimental work different quantities of alum from 0.1 to 2 per cent. have been added; in some instances the whole mixture of toxoid and alum has been used; sometimes the precipitate has been separated from the supernatant liquid and re-suspended after washing in saline. It is not within the scope of this paper to deal with these differences.

The immunity index method of Glenny, Allen, and Hopkins (1923), more fully described by Glenny and Waddington (1928), forms a convenient method of testing antigenic efficiency. Table I shows the immunity index given by the injection into guinea-pigs of 0.1 c.cm. of diphtheria toxoid with and without varying amounts of alum. It will be seen that when alum had been added to the toxoid, 29 guinea-pigs out of 41 were Schick-negative when tested three weeks later, and all were immune by the fifth week. Without alum none, out of 38, was immune after three weeks, and 8 were still Schick-positive seven weeks after injection.

* Since this paper was written, W. H. Park, at the Paris Congress of the International Society of Microbiology, reported 100 per cent. successful immunizations with alum toxoid in small groups of children.

A further series of guinea-pigs was injected with 1 c.cm. of diphtheria toxoid, and the antitoxic titre of serum was tested four to six weeks later. Of 53 guinea-pigs injected without alum, the majority contained 0.02 unit per c.cm. of serum, and the highest value recorded was 0.5 unit; of 23 injected with alum the majority contained 0.5 to 1 unit, and the highest recorded value was 7 units per c.cm. The results of the group are summarized in Table II.

TABLE I.—*Showing the immunity index of guinea-pigs injected with 0.1 c.cm. diphtheria toxoid with and without alum.*

	Number of guinea-pigs giving an index of					
	1	2	3	4	5	Over 5.
With alum	29	10	2	—	—	—
Without alum ...	0	10	12	5	3	8

Alum has also been added to diphtheria toxin used in the hyperimmunization of horses. The average antitoxic value of groups of 50 horses was 696 without alum; with alum 1,102.

TABLE II.—*Showing the antitoxic value of the serum of guinea-pigs four to six weeks after the injection of 1 c.cm. diphtheria toxoid with and without alum.*

	No. of guinea-pigs with antitoxic value of (per c.cm.)				
	Under 0.001 unit	0.001–0.01 unit.	0.01–0.1 unit	0.1–1 unit.	Over 1 unit.
With alum ...	—	—	1	9	13
Without alum	3	6	31	13	0

Many experiments have also been made with tetanus toxoid and alum. Table III gives the results of an experiment on guinea-pigs injected with 0.1 c.cm. tetanus toxoid diluted to 5 c.cm. with saline, or with 0.01 or 0.1 per cent. potash alum. The injections were repeated four weeks later, and the guinea-pigs were injected with tetanus toxin two to three weeks after the second

injection, as a test for the immunity produced. It will be seen that only 3 out of 13 guinea-pigs receiving toxoid without alum survived 1/50 of a test dose of toxin, and out of 4 none survived 1/10 of a test dose. Of the guinea-pigs given alum-toxoid, nearly all survived the injection of toxin, and 4 out of 4 survived 100 test doses.

TABLE III.—*Showing the number of guinea-pigs surviving different doses of tetanus toxin given two to three weeks after the second of two doses (given at four weeks' interval) of 0.1 c.cm. tetanus toxoid diluted to 5 c.cm. with saline or with alum.*

Toxin in terms of test doses.	Number of survivals out of total tested.		
	Diluent Saline.	0.01% alum.	0.1% alum.
0.01	2 out of 4	—	—
0.02	3 out of 13	2 out of 2	2 out of 2
0.05	—	1 out of 2	2 out of 2
0.1	0 out of 4	3 out of 4	2 out of 2
0.2	—	—	2 out of 2
1.0	—	2 out of 2	2 out of 3
10.0	—	2 out of 2	2 out of 2
100.0 (over 20,000 M L D)	—	0 out of 1	4 out of 4

Tetanus alum-toxoid has proved of great service in the immunization against tetanus of horses used for the production of therapeutic serum. The majority of horses given one injection of toxoid with alum have over 1 unit (U.S.A.) per c.cm. of serum four weeks later. Those given toxoid without alum rarely have over 0.001 unit. A comparison between the results with and without alum is given in Table IV. In a further series of 17 horses receiving toxoid without alum, 1 had 0.01 unit, and the others less than this amount, of 155 horses with alum, 124 gave over 1 unit; of these 86 had over 3 units, 20 over 10 units, and 1 had 25 units per c.cm. of serum as a result of a single injection. All the horses were tested before injection, and were proved to contain no normal tetanus antitoxin.

TABLE IV.—*Showing the antitoxic value of horses four weeks after a single injection with 50 or 20 c.cm. tetanus toxoid with varying doses of alum.*

Toxoid.	Percentage of Alum.	Number of horses with antitoxic value of (per c.cm.)			
		0.0002 unit	0.0002–0.01 unit	0.01–1 unit.	1–30 units
50 c.cm.	0.5–2.0	0	1	8	13
10 c.cm.	0.5–2.0	0	1	5	4
50 c.cm.	0.01	8	4	0	0
10 c.cm.	0.01	2	0	0	0

In the hyperimmunization of horses the addition of alum to tetanus toxin has doubled the value of the antitoxin produced. Glenny, Pope, Waddington, and Wallace (1925) showed that if horses were rested for a month or more after a primary stimulus before tetanus immunization was continued, much stronger antitoxin was produced. Ramon and Descombey (1930) have recently confirmed this. Horses with a primary stimulus of alum-toxoid that have been rested at least a month before the commencement of their main tetanus immunization produced an average of 800 (U.S.A.) units per c.cm.

A somewhat similar but smaller effect than that produced by alum has been obtained by Ramon (1926) by the addition of tapioca to toxoid. Ramon, observing that horses developing abscesses at the site of injection yielded serum of higher antitoxic value, tried various substances that would produce sterile abscesses, and eventually chose tapioca as the most suitable. It appears probable that in both cases increased antigenic response is due to delayed absorption. Alum was first tried by us in 1925, when we wished to determine the effect of delaying absorption by presenting toxoid in a relatively insoluble form. My colleague Mr. Pope suggested the use of precipitate as a suitable product. Recent work has confirmed that the original idea is probably correct. Dr. Bazin, continuing this work, has found that several substances which produce relatively insoluble precipitates of toxoid also increase antigenic efficiency. Other work not yet published, has established that toxoid, injected as a primary stimulus, is excreted with extreme rapidity, and that within a few days of injection not 1 per cent. remains in the animal body. The increase in efficiency of alum toxoid is therefore probably caused by its slow rate of absorption, so that antigenic stimulation is maintained for many days. The addition of alum to toxin has also been used with success in the immunization of horses against the toxins of scarlet fever, *B. welchii*, and dysentery.

Summary.

The immunity produced by the precipitate, formed by the addition of alum to tetanus and diphtheria toxoids, is greater than that produced by toxoid alone. The increase in certain experimental conditions has reached even a thousandfold.

TETANY AFTER EXERCISE:

A CLINICAL AND CHEMICAL STUDY OF A CASE.

BY

R. D. LAWRENCE, M.D., M.R.C.P.,

AND

R. A. McCANCE, M.D.,

BENSEM DARWIN RESEARCH STUDENT

(From the Biochemical Department, King's College Hospital.)

Physical Examination.—Nothing abnormal was found. Her pulse was rapid (100), but her heart was normal. Her hands tended to be—and were—rather cold. She was liable to chilblains on her fingers. Her teeth were somewhat soft, and required constant attention.

Experimental Investigation.

As the patient did not always develop tetany after exercise we were fortunate in being able to produce and study it on the morning when she came up from school to the hospital for examination. She was made to exercise vigorously on a stair for fifteen minutes until she was fairly exhausted. She then lay down on a couch, where she remained until she left the hospital. We noticed at once that her respiration rate did not slow down normally after exercise, and, indeed, she continued overbreathing for the next half-hour. Three minutes after she stopped running her pulse rate was 148, and her respirations 52 per minute. The latter were extremely deep as well as rapid; in fact, she seemed to be breathing as deeply and rapidly as she could. At the end of nine minutes* she announced that one of her attacks was coming on, as she could feel the usual tingling in her fingers and a tightness round the waist. In fifteen minutes tetany was fully established; her hands were fixed in the typical position and Chvostek's sign was present. The feet and ankles were slightly, but less, stiff. Knee-jerks were extremely active. The respiration rate remained between 40 and 50 per minute for thirty-two minutes, when she suddenly became apnoeic for about two minutes and the spasms rapidly relaxed. In forty minutes her hands were quite free. Her pulse rate was then 96, and her respirations 22 per minute and very shallow. By sixty-five minutes everything seemed perfectly normal, and she got up none the worse.

Chemical Investigations.

Samples of venous blood were obtained without constriction under paraffin before exercise and fifteen minutes after, when tetany had been fully established for five minutes. Urine was obtained before and again eighty-five minutes after exercise, the latter specimen by catheter as she was unable to pass any urine at this time. The volume of the catheter specimen was only 60 c.cm. The results are embodied in the above table with the changes shown in italics. The alveolar CO_2 was estimated at intervals, but the results were not embodied in the table, as we do not feel that they are very reliable, partly because the subject was not previously trained, and partly because the respirations during overbreathing were so rapid and uncontrolled. Before exercise a figure of 4.62 per cent. was obtained; three minutes after, 3.05 per cent.; and fifty minutes after, 3.8 per cent.

	Before Exercise.	During Tetany.	Methods Used.
	Milligrams.	Milligrams.	
Serum: Calcium	11.7	11 8	Kramer-Tisdall [3]
Plasma: Inorganic phosphorus	*3 6*	*2 51*	Briggs.[3]

Ammonia	*traces*	*0*	Aeration.
Acetone	*0*	*trace*	Rothera.

Duplicate estimations were made in all tests.

* All the times recorded are after the cessation of exercise.

Discussion.

It was clear from these observations that our case fell into the class of tetany due to alkalaemia from over-ventilation. Tonic rigidity of the hands after overbreathing was first described in 1909 by Vernon,[5] and has since been experimentally investigated by Collip and Backus,[6] Grant and Goldman,[7] and Haldane and others.[8] A series of clinical cases has been placed on record by Goldman[1] and Adlersberg and Porges.[9]

It is obvious from the high normal level of the serum calcium that calcium deficiency was not a causal factor. It is possible that the rather high calcium value was due to the parathyroid therapy which had been stopped only four days previously.

The urinary findings are diagnostic. Ammonia disappeared from the urine; traces of acetone were excreted; and the *p*H changed to the maximum possible alkalinity. These changes have all been produced experimentally again and again, and leave no ambiguity. Diuresis is not unusual experimentally, but we did not obtain it.

The blood chemistry merits a little more discussion. Falls in blood phosphate of magnitudes equivalent to ours have been repeatedly obtained by Haldane and others. The majority of the experimental workers have obtained small rises in the serum calcium,[7 10 11] but this has not been universal, even after very prolonged overbreathing. The rise in the *p*H of the blood in this case is of the same order as obtained by Grant and Goldman,[7] but in one respect our results differ from those of the experimental workers. We obtained no fall in the alkali reserve; in fact, a small rise was observed. The fall usually obtained is explained as part of the buffering adjustment made by the body to maintain the normal *p*H of the blood. In our case this must have been entirely absent, and yet the change in *p*H was smaller than many other observers have obtained. We can offer no satisfactory explanation why our results should differ in this one respect from those of other workers, unless it be that our result was obtained with blood collected only fifteen minutes after exercise. The reduction of plasma bicarbonate of some 10 volumes per cent., recorded by other workers, has been after longer periods of overbreathing, usually thirty minutes or more.

The underlying cause of the hyperventilation we regard as "functional." The patient has never been troubled at home, but only at school, and, until recently, after definite matches into which the nervous strain of competition has entered. She has, moreover, been worse lately—since the shock caused by the sudden death of her head mistress. We classify her case, therefore, with those due to alkalaemia from over-ventilation recorded by Goldman[1] and Adlersberg and Porges[9] in hysterical and post-epileptic subjects.

Summary.

A case of tetany after exercise has been investigated and found to be due not to the exercise *per se*, but to an alkalaemia caused by prolonged (presumably functional) overbreathing after the exercise was completed.

Our thanks are due to the excellent co-operation of the patient in a rather arduous investigation, and to Mr. Mann of the Maudsley Hospital for estimations of the blood *p*H.

FAMINE OEDEMA.

BY

W. R. WYKROYD, M.D. T.C.D.,

BEIT MEMORIAL RESEARCH FELLOW

FAMINE, war or hunger oedema is defined by Nixon[1] as a form of dropsy associated with bradycardia, polyuria and asthenia, occurring in persons subjected to prolonged underfeeding. The "epidemic dropsy" of Bengal may be the same disease, Grieg[2] having found evidence of its association with faulty nutrition; but the dietetic origin of epidemic dropsy is not accepted by all. Famine oedema has been thought to follow either an actual lack of calories or deficiency in a particular food factor. Clinically oedema has been found at times associated with all the deficiency diseases except rickets. Bloch noted its occurrence in some cases of keratomalacia. Falta[3] recorded the fact that the victims of war oedema sometimes suffered from night-blindness. There is little doubt that both keratomalacia and night-blindness occur in those whose diets are deficient in vitamin A. Bigland[4] recorded famine oedema as a clinical entity in close association with an epidemic of pellagra, and found that more than half the pellagrins observed suffered from concurrent dropsy. The superadded oedema which makes the difference between a wet and a dry case of beri-beri is very similar in its nature to famine oedema, and wet beri-beri and famine oedema are so closely alike as to have been often confused. The 'ship beri-beri' described by Nocht[5] in which symptoms of peripheral neuritis rarely occurred, was possibly famine oedema. Similarly, dropsy is sometimes a symptom associated with scurvy, and cases of famine oedema have been recorded with spongy gums and other scorbutic lesions.

In man, vitamin deficiency diseases do not often occur in those whose diets are complete except for the one missing factor. Occasionally a full diet may be lacking in one vitamin only, as, for example, the diets of polar explorers which may be devoid of vitamin C, but otherwise complete; or perhaps the generous rations of an army in the field which may be deprived of the antineuritic vitamin by sterilization and prolonged cooking in water containing alkalis. But as a general rule vitamin deficiency disease occurs in the very poor, the half-starved and the victims of war or famine conditions, who can get only the very minimum of the cheapest food necessary to keep body and soul together.

The experimental reproduction of various deficiency diseases (such as keratomalacia, infantile beri-beri, scurvy and rickets, adult beri-beri cannot be precisely reproduced in the laboratory) which enables the distribution in foodstuffs of the various vitamins to be worked out has done much to explain the epidemiology of deficiency disease in man. It is not always easy, however, to explain the *geographical* incidence of deficiency disease in terms of the vitamin hypothesis—to explain why, for example, a wretched diet of milled cereals leads to pellagra in South Carolina, to beri-beri in Java and Newfoundland, to scurvy on the Rand. The diets associated clinically with various deficiency diseases often seem equally deficient in all the known vitamins in addition to fat, protein, and mineral salts.

It is therefore a feasible hypothesis, since "hunger oedema" has been noted in association with almost all the deficiency diseases and these in man are usually associated with general mal- or under-nutrition, to regard the oedema as due to a shortage in one of the dietary fundamentals other than vitamins, such as fat, protein, or mineral salts. It has occurred on a regime composed very largely of root vegetables, and the oedema noted in Germany during the war, in infants on a diet almost entirely cereal was probably a similar condition. The most exhaustive account of the disease is that of Schittenhelm and Schlecht, who during the war investigated an outbreak in a labour corps attached to the German Army. They came to the conclusion that excessive intake of fluid and protein starvation accounted for the condition.

Harden and Zilva[6] produced oedema in a monkey fed on a diet deficient in vitamin A. The basic diet consisted mainly of polished rice with an addition of yeast to supply vitamin B and a thin tar iron complex. Beri-beri attributes the oedema occurring in Danish children during the war to excess of carbohydrate, though in a certain proportion of cases showed xerophthalmia (vitamin A deficiency). In other cases of xerophthalmia and [illegible] malacia oedema did not occur, and these children had usually been nourished on skim milk which contained vitamin in abundance, though little vitamin A or fat.

There is in fact little convincing evidence to connect famine oedema with vitamin A deficiency. On the other hand the evidence seems to point to shortage of protein as the most likely cause. Kohlman[7] produced oedema in rats by feeding them on diets containing a high percentage of carrots and thus low in protein. Butter-fat and wheat germ were given as sources of vitamin A, B and D, and mineral salts were also supplied. Addition of purified casein to the diet prevented the appearance of oedema. It is probable that Kohlman's diets were low in the factor ("pellagra" vitamin (B)) but oedema does not usually point to deficiency of this factor.

Clinically famine oedema seems to respond to a good all round diet, probably containing all the dietary essentials. The oedema of wet beri-beri clears up rapidly under treatment by diets rich in vitamin B_1 (antineuritic), but such diets are usually rich in other factors also.

The case about to be recorded was observed at St. Anthony Hospital, North Newfoundland. For a variety of reasons the poorest Newfoundland families in late spring and early summer may be reduced to a diet made up almost entirely of white flour bread with very scanty additions in the form of molasses, salt meat and salt fish and little else. At times the additions may run out and the family be reduced to bread and molasses. Such a regime usually produces beri-beri, a common disease in Newfoundland.

Newfoundland beri-beri is identical with the tropical rice-eater's disease and both wet and dry forms may be observed, the latter being by far the commoner.

CASE

A. C., 39, [illegible] single woman, was admitted to St. Anthony Hospital on July 23rd, 1929, complaining of swelling in the abdomen and legs. She stated that she had begun to notice the swelling which had appeared first in the legs quite suddenly about three weeks before admission. She complained of considerable general weakness, especially marked in the arms and legs, as in beri-beri. There was no marked shortness of breath and vomiting and headache were absent. Constipation was a prominent symptom.

She gave the following dietary history. She and her father, an old man incapable of work, lived alone in circumstances of extreme poverty. For six months before admission they had been able to get only dry bread and molasses to eat and for some previous time their diet had not been far above the level. Sometimes on Sunday, when neighbours were charitable, they had a little salt meat and during the sealing season (April) they had three meals of seal meat. Otherwise the patient had subsisted for six months on bread, molasses and tea. She and her father had never been particularly hungry.

Examination showed a cachectic looking patient. The skin had a peculiar yellow tint. Severe emaciation was evident, which however was not marked by dropsy. The pulse rate was about 80, the [illegible] was no rise of temperature. The heart was not enlarged, the sounds were clear and had not the muffling and tachycardia of the beri-beri heart. The abdomen showed marked ascites and the legs were generally oedematous. Oedema was also present over the sacrum and the base of the lungs were congested. There was no evidence of peripheral neuritis. The right knee-jerk was sluggish, the left normal. No areas of anaesthesia could be discovered. Scorbutic signs were absent. There was a trace of albumin and casts. The output being about 10 oz. per day.

A blood count showed red blood cells 2,000,000 per c.mm. White blood cells 4,200, haemoglobin 60%, no change in size or shape [illegible] showed no marked alteration in shape or size. [illegible]

There was a previous history of [illegible] having been in hospital in 19[illegible] suffering from [illegible] which had proved [illegible]

subjects there was a lymphocytosis which usually began on the second day after administration of the drug and continued for at least four or five days. In the tuberculous cases a similar change occurred when benefit resulted from the treatment. The greater the benefit the greater and more prolonged was the rise in lymphocytes. When, however, an injection produced a bad effect on the disease the lymphocytes fell from the beginning. In three of the patients there was an increase in the eosinophils. Eosinophilia seems to be a frequent result of sanocrysin treatment in tuberculosis.[3]

As far as these results go they show that improvement under sanocrysin treatment in pulmonary tuberculosis is accompanied by leucocytic changes resembling those that occur during the spontaneous cure of the disease, and that similar variations in the leucocytes are produced in non-tuberculous subjects by small doses of this drug. When, however, sanocrysin produces a bad effect on tuberculous patients the blood changes resemble those that are seen when the disease is progressing. If, as is usually believed, the changes in the blood picture are an indication of the degree of resistance to the disease, it would appear that the action of sanocrysin in tuberculosis resembles that of a vaccine in that it stimulates curative processes which are already going on. This idea is supported by clinical experience, for it has been found[6 7] that sanocrysin gives the best results in patients whose resistance is not undermined, and in whom the natural forces of the body have to some extent checked the progress of the infection. On the other hand it does harm when, owing to overwhelming toxaemia or other causes, the tissues are not capable of responding to stimulation or when the dose is too large. The administration of this substance should therefore be controlled by the laws governing vaccine therapy, as has been suggested by Cummins.[1] The extent to which the size and spacing of doses can be controlled by the changes in the white blood cells is a matter for further investigation.

Burrel[6] is of the opinion that the production of a reaction and the stimulation of the tissues to kill tubercle bacilli are two different actions of the drug. The changes seen in the blood picture two hours after injection support this view. There is generally a fall in the total leucocytes with relative neutrophilia. The other complications that are occasionally seen—namely, albuminuria, gastro-intestinal symptoms, erythema, and rheumatic pains and aches—are probably due to direct toxic action of gold.

Summary.

The blood changes following injection of sanocrysin have been studied in four patients suffering from chronic pulmonary tuberculosis and in two unaffected persons. They suggest that the chief action of this drug in pulmonary tuberculosis is to stimulate the curative processes already going on in the body.

Our thanks are due to Major H. S. Anand, I.M.S., professor of physiology, King Edward Medical College, Lahore, for permission to work in his laboratory, and to Drs. Shujaat Ali and Baldeo Singh Bhandari for assistance during the investigation.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

HENOCH'S PURPURA REQUIRING SURGICAL INTERVENTION.

CERTAIN unusual features in the following record of a case of Henoch's purpura may render it of general interest.

A man, aged 23, complained of joint pains on April 27th, 1929, and Dr. Scales of Radstock, who saw him on the same day, found petechial haemorrhages on both patellae and olecranon processes, associated with slight pyrexia. Seven days later abdominal pain developed; it was severe on movement, and there was vomiting and constipation. Four days after the onset of these symptoms I saw him with Dr. Scales. The vomiting and constipation were continuing, the patient looked ill, and the temperature was raised, the pulse rate being 120. The abdomen was distended and tympanitic, and the pain was severe.

The diagnosis of Henoch's purpura was considered doubtful on account of the patient's age, and since it seemed clear there was an abdominal emergency I operated the same day. Several pints of straw-coloured fluid came away, and some coils of distended small intestine appeared. On exploration I found a thickened piece of small intestine; it was deeply congested, with numerous subperitoneal haemorrhages throughout a length of two feet. The walls were greatly thickened by oedema, and the gut felt like a piece of hose-pipe. The intestine was distended above and collapsed below this. Since it was evident that acute obstruction existed, I performed a short-circuit of ileum to ileum, thinking the gut would recover. Forty-eight hours later an enema produced a satisfactory result. One week afterwards a faecal fistula appeared, only to close three or four days later. Whether this was due to the breaking down of my anastomosis or to gangrene of the loop I do not know. The patient's recovery was uneventful except for three attacks of colic when solid food was first eaten, but several more crops of petechiae, with pyrexia, appeared.

When seen on June 28th this year he was very fit and active. The bowels were acting well without aperients, but after a large meal there would be fullness and slight pain, with gurgling in the lower abdomen. This disappeared immediately on defaecation. There was a slight fullness of the lower abdomen, with visible peristalsis and gurgling at the upper end of the wound, which had firmly healed.

I consider the case unusual because Henoch's purpura is found in children, and resolves without operation. With reference to the last point, I operated on an adult male for a simple inguinal hernia, and exposed in it one foot of small intestine, with its walls half an inch thick. I resected it, and found the lumen the diameter of a lead pencil, the mucosa being normal. It is possible that this was a sequel to an attack of Henoch's purpura in childhood, or to an intussusception resolving spontaneously. I consider that it would have been sounder surgical procedure in the first case to have resected the gut.

I wish to thank Dr. Scales for his permission to publish this case.

EPITHELIOMA OF THE LIP DEVELOPING ON THE SITE OF RECURRENT HERPES SIMPLEX.

IN view of its unusual etiology the following details of a case of epithelioma would seem to merit being recorded.

On June 12th I was consulted by a man, aged 57, a non-smoker, on account of a lesion of the lower lip. He stated that for the past two years he had suffered from frequently recurring crops of blisters on the left side of the lower lip. These blisters always appeared on the same spot, and although there were intervals between the attacks the lip never returned to its normal condition.

On examination a lesion about the size of a threepenny-piece was seen; it was situated on the left side of the lower lip, half-way between the centre of the lip and the angle of the mouth. Its anterior half was covered by a brown, readily bleeding scab, while in the posterior part several closely set unruptured herpetic vesicles were present. There was very little induration and no enlarged lymphatic glands were palpable.

In view of the chronicity, and of the clinical appearances of the anterior portion, I considered excision advisable, and performed the operation. I considered excision advisable, and performed the operation of patient to Mr. Duncan Wood, who performed the operation on the next day. The pathologist reported that the case was one of an epithelioma. The patient has since been given further treatment with radium.

This case is interesting on account of the unusual predisposing cause for the epithelioma. The patient is a non-smoker, and one can only assume that the chronic irritation of the recurring herpetic eruption led to the malignant changes.

Hon. Assistant Physician, Skin Department, Bristol General Hospital.

Reviews.

THE CEREBELLUM.

Wide discrepancies exist between the clinical and the physiological interpretation of the functions of the cerebellum, and the time appears ripe for a correlation of evidence derived from the two sources. One therefore approaches a new monograph on the subject of the cerebellum with a sense of high expectancy. The present volume,[1] the sixth of a series of neurological monographs published by the Association for Research in Nervous and Mental Disease, is based upon the proceedings of their "cerebellar" meeting held in New York on December 28th and 29th, 1926. It contains twenty-two separate papers on the cerebellum, some compiled from secondary sources, some from original work, but apart from the paper of Larsell the volume contains little that is new, however useful it may prove as a summary of existing knowledge. The material is arranged in five sections: morphology, physiology, pathology, clinical symptomatology, and treatment; individual papers have been carefully edited, but, like so many compilations of this character, the work lacks an underlying theme, and the reader rises from its perusal without fresh perspective and with a sense of general disappointment. The attempt to correlate cerebellar symptomatology of human beings with recent physiological work has been unsuccessful, for the writers representing these fields have not met on common ground, and none of them seems to be thoroughly familiar with both aspects of his subject.

The first section of the book contains O. S. Strong's stimulating paper on unsolved problems suggested by cerebellar connexions and cerebellar histology, followed by H. A. Riley's comparative study of the folial patterns of the mammalian cerebellum, both of which have already appeared in the *Archives of Neurology and Psychiatry* (vol. 19, 1–30, 1928; vol. 20, 895-1034, 1928). There are two well-illustrated papers on the proprioceptive end-organs, based on secondary sources, which contain useful bibliographical references; the first by A. Elwyn deals with the structure and development of the proprioceptive organs, and the second by C. M. Byrnes is concerned with their comparative morphology. Of exceptional merit is Olof Larsell's contribution on the comparative morphology of the membranous labyrinths and the lateral line organs in their relation to the development of the cerebellum, which is based almost entirely on the writer's own studies. This paper, and the fruitful discussion of it which followed after it was read, may be recommended as a clear and authoritative discussion of the phylogenetic origin of the cerebellum. He accepts Ingvar's division of the neo- and paleo-cerebellum as modified by Bremer. L. Hausman's studies of the comparative morphology of the cerebellar vermis are based upon first-hand knowledge, and provide a valuable discussion of the older parts of the cerebellum. The section on the physiology of the cerebellum, though weak, contains a useful summary by Professor F. R. Miller of the University of Western Ontario. Full details are given concerning his experiments, already familiar to workers in this field, on the stimulation of the cerebellar nuclei. Aubrey T. Mussen once more sets forth his evidence for the localization of function in the cerebellum on the basis of his stimulation experiments with the stereotaxic instrument of Horsley and Clark. Mussen claims to have destroyed the red nucleus without significant injury to the other parts of the nervous system, and sections are given showing the degenerations resulting from such a lesion, but no description is given of how this remarkable feat was accomplished. Mussen still maintains that the cerebellar hemispheres are excitable, and holds on slender grounds that a mosaic of sharply circumscribed centres can be delineated as in the motor cortex of the cerebrum. L. J. Pollock and L. Davis point out that when the cerebellum is removed from a decerebrate animal labyrinthine reflexes become augmented, and decerebrate rigidity increased. L. B. Hohman reports upon the degenerations resulting from isolated lesions in the cerebellar cortex of cats, finding among other things that there are no direct efferent pathways to the pons, mid-brain, or spinal cord, and that all cortical fibres have a first synapse in the deeper cerebellum nuclei, except those which pass from the anterior vermis to Deiter's nucleus.

The pathological section, which concerns itself wholly with cerebellar connexions, consists of two papers: one by L. H. Cornwall, who describes a series of histological observations in a kitten with congenital atrophy of the cerebellum, and another by N. Winkelman and J. L. Eckel on the origin of the cortico-cerebellar system, based upon fourteen human cases with lesions in various parts of the cortex. The clinical section contains an excellent paper by T. H. Weisenburg on cerebellar symptomatology, and other papers giving analyses of individual symptoms such as nystagmus (Favill) and arrhythmokinesis (Wertham and Lyman). In the section on treatment Adson and Parker point out the advantage of surgical diathermy, and they stress the value of the Cushing crossbow incision as giving a more satisfactory exposure for cerebellar explorations; the paper is well illustrated, and contains interesting statistical information. H. K. Pancoast and F. C. Grant describe a series of forty-eight tumours which have been treated by x rays and insist that only the more virulent—for example, the medulloblastoma of Cushing and Bailey—are benefited; they insist that adequate radiation depends upon exact localization at operation.

The book is thus indispensable as a guide to recent work, whatever the shortcomings may be of individual papers or of its general scope. Though there are minor typographical errors in nearly every bibliographical list, and though such grotesque spellings as "technic" for technique are permitted, the book has the saving grace of an admirable index.

LIVER TREATMENT IN ANAEMIA.

The short volume of the Modern Treatment Series by S. C. Dyke, entitled *Liver in the Treatment of Pernicious and Other Anaemias*[2] is just what has been wanted by all medical practitioners. The author is thoroughly well fitted for his task, and the book is written in a concise clean-cut style, which is most attractive. Facts are set down without padding, and where accurate knowledge is wanting this is clearly stated.

The first two chapters give a short history of the pathology and methods of diagnosis of pernicious anaemia, and although occupying only twenty-two small pages together, the account is clear and nothing of importance is lost. One point only may be mentioned. The author is dogmatic in his statement that the presence of the smallest amount of free hydrochloric acid in a single specimen (of a fractional test meal) is sufficient to negative a diagnosis of pernicious anaemia. This is in fact not strictly true, since rare cases of fatal pernicious anaemia, with all the characteristic morbid anatomy, have been recorded in which free hydrochloric acid was present in the gastric juice throughout the disease. Dealing with the liver treatment of pernicious anaemia Dyke, in a foreword, acknowledges his debt to Minot of Boston, who has criticized the pages dealing with the history of the new great advance in therapy, and this point naturally enhances the value of this section of the book. Ample credit is given to the pioneer work of Whipple and his colleagues on the post-haemorrhagic anaemias in animals, and the recovery which followed the administration of various diets. The whole history of Minot's early dietetic work, and his gradual recognition of 250 grams of liver as the basic and essential principle, is given in full. The development of the production of liver extracts, and also suitable menus for patients on liver diet, are detailed.

[2] *Liver in the Treatment of Pernicious and other Anaemias.* By S. C. Dyke, D.M.Oxon., M.R.C.P.Lond. The Modern Treatment Series. London: J. Cape. 1930. (Cr. 8vo, pp. 131; 6 figures. 5s. net.)

rise to them. Questions on adenoids do not appear in association with those on disease in children, a question on "quinsy" appears in one section and a question on "acute tonsillitis" in another, divided from it by more than fifty pages. It is curious, and seems worth notice, that two on adenoids and four on the tonsils were the only questions on these subjects during the nineteen years, and that during this period only two questions were asked about appendicitis. Questions on typhoid continue to be relatively frequent, while there seem to be none on influenza. In the section headed "Diseases of bone, fractures, and dislocations" are found nineteen questions on diseases, thirty-two on fractures, and only two on dislocations. Diseases of joints and deformities are in another section. The examiners' neglect of dislocations is rather remarkable.

A survey of this compilation leads to the impression that the questions in midwifery are the easiest to answer on paper (though among the most difficult to put into practical application thereafter), that there are a number of questions which have become almost traditional, and that it might be a very good thing if, one of these years, the examiners were to surprise the examinees with a whole series of questions entirely unrelated to those set forth in this book.

AMBROISE PARÉ.

So much has been written about the great man who was the Father of French Surgery that it is not easy to say anything new about him or to add much to what is already known. It is possible, however, to present the facts in a new way, and this DR. LÉON MICHELET has done with great success.[6] He has taken certain incidents in Paré's life and has surrounded each with a frame, which enables the reader to understand their true significance. To do this satisfactorily a writer must be well fitted with a knowledge of French history during the sixteenth century—general, social, and professional—and in each branch Dr. Michelet shows himself to be well equipped. The setting, of course, is imaginary, but it is so near what probably happened as not to be much out of keeping with the truth. The book can therefore be read with pleasure by the scholar who knows, as well as by the general reader who wishes to learn. Dr. Michelet has not tried to solve any of the problems in connexion with the life of Paré. He accepts the date of his birth as 1509, he believes him to have been a Protestant, and he uses as a frontispiece the portrait dated 1581. DR. VICTOR PAUCHET contributes a preface in which he seeks to interpret Paré's character from phrenology by Paul Nyssens of Brussels, from his handwriting by Camille Streletski, and by Dr. Leopold Levi using "endocrinological methods." These methods show, it is said, that the portrait—seemingly he only used one—proves Paré to have shown signs of "hyperpituitarism, hyperthyroidism, and hypergenitalism."

NOTES ON BOOKS.

WITH the help of DR. GEORGE ALEXANDRESCU, formerly assistant at the Institut d'Histologie, and physician to the hospital at Bucarest, DR. SERGE VORONOFF has published a short book on *Testicular Grafting from Ape to Man*,[7] which has been translated by Dr. Theodore C. Merrill. Dr. Voronoff wishes to emphasize the point that his results have been due to a special and personal grafting method "which has nothing in common with methods of other operators." He proceeds, therefore, to give a detailed description of his method, accompanied by very good illustrations of each step in the operation. The rest of the book deals with the results of the examination of testicular simian grafts removed from man after periods never hitherto attained. Histological sections, studied by Professor Retterer of Paris, have proved the prolonged survival of the glandular cells in the simian grafts, and the perfect correlation existing between physiological phenomena observed after grafting and histological changes in the grafts. The authors' conviction is that the true germinal cells of the graft, those of the primary tubules constituting the mother cells of the adult tubules, together with the cells of Sertoli, have the principal, if not the exclusive, function of producing the testicular hormone. They assert that the rôle of the interstitial cells in producing the hormone is completely disproved.

We have received from the Library of the North Caucasian Association of Scientific Research Institute a Russian monograph,[8] with a German summary, by Professor K. MIRAM, on a Red Cross expedition in September, 1928, to the Adyge district in North Caucasus. The purpose of the expedition was to inquire into the mode of life, physical development, and diseases prevalent among the Adyge, a primitive Circassian race, whose chief source of livelihood is agriculture and the breeding of cattle. Measurements showed that while the men exceeded Topinard's average in size, the women were 6 to 7 per cent. below it. The principal diseases found in the country were malaria, tuberculosis, goitre, syphilis, and gonorrhœa, the last of which was probably responsible for the decline in the population.

DRS. E. LESNÉ and M. COFFIN have contributed to the modern French series of "Paediatric monographs" a useful little book entitled "Vomiting in Infancy."[9] Their general scheme for examination of infants with vomiting as the main symptom is very sound and inclusive, while the classification of vomiting follows orthodox lines. Particularly interesting is the section on spasms of the stomach and pylorus, with useful hints on treatment, while there is a very good account of hypertrophic pyloric stenosis, with some of the results of operation in these cases. This is one of the first books to contain a record of pyloromotomies as performed by Fredet in France for this condition, and the results are contrasted with those obtained in other countries.

PREPARATIONS AND APPLIANCES.

A PRIVATE INVALID CARRIAGE.

A PRIVATE invalid carriage has been built for the Daimler Hire Company by Mann, Egerton and Company, of London and Norwich, consulting engineers to the Medical Insurance Agency. It will be recalled that this firm designed, also on a Daimler model, the ambulance which was used to convey the King from London to Bognor Regis in the early part of last year, a vehicle which was described and illustrated in these pages at the time. The new carriage, built on a 57-h.p. Daimler chassis, which has the longest wheel base of any private car chassis made, is so evenly balanced that in spite of its ample proportions it appears to be no longer than the modern high-powered limousine. The stretcher bed which it contains has been designed to give entire comfort and to prevent road shock or vibration. A specially designed mattress on a chromium-plated frame is mounted on a swivel under-carriage, the whole arrangement swinging round to facilitate the removal of the stretcher. Comfortable seating accommodation is also provided for the professional attendant and for any friend accompanying the patient. The interior decoration and appointments—the pile carpet and sponge-rubber floor covering, the compact and unobtrusive arrangements for the washbasin and sick-room appliances, the heating by a specially designed hot water radiator, the ventilation by louvers fitted above the sidelights, the lighting by four electric lamps fitted flush into the roof, the precautions to prevent entrance of fumes and to deaden noise, combine to make the equipment of this vehicle a notable example of the art of ambulance design.

INVALID FURNITURE.

We have received from Messrs. John Ward, Limited (246, Tottenham Court Road, W.1), a catalogue of their latest invalid furniture, a branch of craftsmanship in which they have specialized for many years. Scores of models of couches and chairs are exhibited. One pretty device is a spring frame made up of very strong coil springs, laced together by a material which stops all creaking. So long as the patient lies flat nothing happens, but if the head is raised an inch or two from the pillow the top section of the frame gently follows it until the invalid is completely supported sitting up, and at the same time the other two sections—all three sections being hinged together—come into a position which raises the knees to a restful, half-bent attitude, and prevents slipping. The wheeled-chair is reproduced in as many designs as there are infirmities, perhaps in as many as there are patients' fads to be humoured, and the utmost ingenuity has been exercised in diminishing vibration and the other irritations experienced in a chair and couch existence. A study of the catalogue shows how very effective a part of the nursing service upholstery has become.

EVOLUTION OF INFECTIOUS DISEASES.

Infectious disease is not the static thing which the young student of medicine pictures to himself, but a biological phenomenon reflecting the living characters of its reagents; it tends ever to change, to undergo evolution. The observations made over so short a period as a century reveals this tendency, for in this compass of time diseases like syphilis and pneumonia have undergone a change. But even though this tendency were not manifest a little reflection would teach us that it must exist, for the agents of disease are of the simplest forms of life which must at first have lived a saprophytic existence. Only later, when higher forms of life appeared, could some of these microbes take on a parasitic and pathogenic role, and it is impossible to conceive of this change being anything but gradual, so that an infectious disease as it presents itself to us to-day must inevitably differ from what it was like at its inception. How have these diseases originated? Will they always be with us, or will some disappear and new diseases take their place? Many have pondered on these questions, among them Charles Nicolle, eminent investigator and director of the Pasteur Institute, Tunis, who has now given us the fruit of his reflections in a small book entitled *Naissance, Vie et Mort des Maladies Infectieuses*.[1]

Nicolle pictures the birth of an infectious disease, the saprophytic bacterium gaining access to the mammalian tissues and perhaps once in a way establishing itself in this new environment, the newly acquired function being perpetuated and the power of invasion—virulence—becoming increased by passage, the whole process being governed by chance, with the successes vastly outnumbered by the many abortive attempts in this new direction. He imagines, and probably with reason, that an infectious disease in its infancy must pass through a phase in which infection is symptomless, an "*infection inapparente*"—a phenomenon which can be produced experimentally as Nicolle has shown us, and which occurs naturally and plays an important part in the spread and perpetuation of epidemics. Gradually, the fully developed disease is evolved, the transition from the endemic to the epidemic form occurring readily where direct contagion is possible, or, in the case of a disease common to man and other mammals spread by an insect vector, by the adaptation of the virus to an insect parasite peculiar to man. Nicolle cites the relapsing fevers as an example of the latter phenomenon—the European variety spread by the body louse being the only one to assume epidemic proportions; another example would be typhus and the typhus-like diseases, such as the scrub typhus of the Malay Peninsula and Rocky Mountain spotted fever.

The future of infectious disease is of even greater interest to us. In a strictly isolated and uncivilized community, debarred of all aid from medical science, one can imagine that in course of time the herd immunity to the prevalent diseases would be so raised that these would become progressively milder, some finally disappearing, having passed through the phase of "*infections inapparentes*" in the process. Presumably these disappearing diseases would be replaced by new ones. But no such strictly isolated communities exist nowadays, or, if they do, modern methods of communication will soon deprive them of their security, and the constant influx of susceptibles, the world-wide comings and goings, will see to it that Nature is deprived of her one method of dealing with infectious disease. On the other hand, civilization and learning have given us many weapons to use in our war against disease. A higher standard of social well-being and personal cleanliness has reduced the incidence of the body louse in this country, and in consequence typhus fever no longer occurs. Quarantine measures and the slaughter of affected animals have rid this island of such diseases as rabies and glanders. Specific prophylactic and therapeutic measures have enabled us to reduce the incidence of some diseases and render the effect of others less serious, so that in civilized communities contagious disease can be controlled. But with the ever-increasing facility of travel and communication existing diseases become more widespread, unless they are limited geographically for some special reason, as in the case of trypanosomiasis, for example, with the result that civilized man will suffer from a greater variety of contagious diseases, but will have less to fear from them so long as he fights them relentlessly, making full use of his knowledge and ingenuity.

Nicolle's essay reveals his fertile mind and literary abilities. Many will not agree with all he says; he does not expect general agreement; but if the book serves to stimulate thought, as it assuredly will, his purpose will have been achieved.

THE BRITISH RED CROSS SOCIETY.

The British Red Cross Society, which was founded in 1870, celebrated its diamond jubilee on August 8th. Sixty years ago, during the anxious days of the Franco-German war, Colonel Loyd Lindsay, V.C., afterwards Lord Wantage, issued an appeal for the organization of a National Aid Society which should minister to the sick and wounded soldiers. Distressing reports of the sufferings which were being endured had reached this country, and there was an immediate and generous response—a fund opened by the Lord Mayor of London reached £200,000, and forty doctors were immediately sent overseas, twenty to France and twenty to Germany. Before hostilities ended two hundred workers entered the fighting area. The conclusion of this war left the society with surplus funds; these were partly expended on the training of women nurses at the Royal Victoria Hospital, Netley—a group from which evolved the Queen Alexandra Imperial Military Nursing Service. The society continued its activities through the Turco-Serbian war of 1876-77, the Russo-Turkish war which followed, the Zulu war of 1879, the Transvaal war of 1881, the Egyptian expedition in 1882, the Soudan campaign in 1884–85, the Serbo-Bulgarian war of 1885–86, the Rhodesian expedition in 1896, the Greco-Turkish war in the following year, and the Sudan campaign of 1898. During the South African war the Central British Red Cross Committee was responsible for two hospital trains and a hospital ship; it also supervised many hospitals which had been privately fitted out, and arranged for the supply of doctors and nurses, and the collection and dispatch of medical stores. In 1908 the Central British Red Cross Council and the National Society for Aid to the Sick and Wounded in War were incorporated by Royal Charter. In the recent war the society became a vast organization related with the Army Medical Services,

and a joint committee of the British Red Cross Society and the Order of St. John of Jerusalem received the official recognition of the War Office. This committee administered *The Times* Fund of £22,000,000, providing ambulances, hospitals, and sanatoriums, and easing the transport of wounded and disabled men on every front. The magnitude of the work undertaken needs no emphasizing, but mention may well be made of the efforts to trace wounded and missing soldiers, to aid the incurably maimed, and to relieve and rescue the hapless refugee populations of Southern Europe.

After the war the British Red Cross Society was encouraged by the League of Nations to direct its energies towards the maintenance of public health, and in 1919 a supplemental Royal Charter gave it authority to do so. During the last ten years the history of the society has been one of transition; gains have been consolidated, and new services organized. The majority of the auxiliary hospitals were closed on the discharge of their inmates, though a few remain as convalescent homes or special hospitals. Starting with the motor ambulances still in use when the war ended, a home ambulance service was built up in 1919 *to provide more efficient transport for the sick and* injured, especially in rural districts, and there are now more than 350 ambulances either affiliated or belonging to the service, including the mobile *x*-ray service. The society is also in charge of a blood transfusion service for London hospitals. About seven hundred lectures on health subjects are given in country districts every year; dispensaries are established in hop-fields, and dressing stations in the herring-fishing centres. The well-known Voluntary Aid Detachments, which during the late war released many thousands of trained men and women for service abroad, continue to provide an elaborate system of instruction, which is very widely welcomed. A more recent development of the society's work is the equipping of a clinic in London for the investigation, diagnosis, and treatment of chronic rheumatism.

THE PASTEURIZATION OF MILK IN CANADA.

In his annual report for 1929 Dr. A. J. Douglas, medical officer of health for Winnipeg, includes an interesting summary prepared by the chief dairy inspector of the city setting forth the extent to which the pasteurization of milk is practised in thirty-two Canadian cities, mostly with populations of 20,000 and over. In three of these—namely, Saskatoon, Sask., and the Ontario cities of Hamilton and Niagara Falls—all the milk sold is pasteurized. These are closely followed by Toronto and Windsor with 99.5 per cent. of milk so treated. Then come Ottawa, Fort William, and Verdun (Quebec) with 98 to 98.5 per cent. Of the thirty-two cities precisely one-half, including those named above, provide their inhabitants with a milk supply of which 90 per cent. or more has been pasteurized. In all the rest there is some pasteurization, and in most of those where the pasteurized moiety is low the rest of the supply or the whole supply is protected by the tuberculin test. Comparison is made in the report with the measures adopted in the United States, regarding which it is noted that in practically every large city 90 per cent. or more of the milk is pasteurized, while in twenty-one cities the whole supply is required to be submitted to this process. In the city of Winnipeg itself the proportion of pasteurization is 62.6 per cent., the balance of the supply being 1.4 per cent. certified and 36 per cent. derived from tuberculin-tested herds. The view is expressed by the chief dairy inspector that this proportion is too low, and that the effort should be made to reach the 99 per cent. level as early as possible. While the data summarized reflect the importance attached to pasteurization in North America, it is desirable at the same time to point out it is not necessarily, in the cases quoted, employed as a rival to other means of protection, as it often is in this country. The graded milks of the United Kingdom include, for example, a certified milk which is tuberculin tested, a Grade A milk (tuberculin tested), and a pasteurized milk, but the three grades are distinct from one another, and neither a certified nor a Grade A milk (tuberculin tested) may be pasteurized. In the Canadian summary, on the contrary, in several of the cities pasteurization appears to be applied to the milk of tuberculin-tested herds. The guiding principle is enunciated in the Winnipeg report in the following terms: "Pasteurization is the final safeguard which should be applied to all milk after all other precautions governing production and shipment have been taken; but pasteurization should not be used as a smoke screen for covering up or hiding the contaminating ills lurking behind unhealthy herds, unsanitary premises, battered equipment, unclean and careless methods." Experts in Great Britain will cordially agree with the latter portion of this pronouncement. With regard to the former they will prefer to think that where adequate precautions have been taken pasteurization *is needless. At the same time, it must be conceded* that where milk has been exposed to infection of human origin, despite routine precautions, pasteurization may prove of service in preventing outbreaks of milk-borne disease among consumers in Great Britain as in America.

MENTAL HYGIENE.

An important symposium is contained in the recently published Part III of volume cxlix of the Annals of the American Academy of Political and Social Science, Philadelphia, under the title *Some Social Aspects of Mental Hygiene*,[1] and edited by Dr. Frankwood E. Williams, medical director of the National Committee for Mental Hygiene, New York City. The twenty-one articles are all by American writers, and are arranged under three main headings—"General Aspects of Mental Hygiene," "Mental Hygiene in Education and in Mercantile Life," and "Institutional Treatment and Community Organization." The articles naturally vary in length, value, and importance, though there are but few without some noteworthy observation. Many of them are so sketchy as to be of little practical use either for thought or for application, but a few of them are of great value in both respects. Special attention may be drawn to the introductory article by the editor, entitled "Finding a way in mental hygiene"; to two articles by Dr. Edgar A. Doll, the director of research at the Vineland Training School, entitled respectively "The mental health value of special education" and "Community control of the feeble-minded"; to the contribution entitled "Mental hygiene in preventive medicine," by Dr. William Russell, professor of psychiatry in Cornell University; and to that on "The child of very superior intelligence," by Dr. Leta S. Hollingworth, professor of education, Columbia University. In an article, too, on "Eugenic sterilization in the United States: its present status," Mr. Frederick W. Brown, the director of the Department of Information and Statistics of the National Committee for Mental Hygiene, New York, gives a complete and convenient account of the sterilization laws in the twenty-four States which have such enactments, and the extent to which, and manner in which, those laws have been put into application. The author appends to his article a selected annotated bibliography on sterilization, both pro and con; and if in connexion with all this information there be read the second of the articles by Dr. Doll named above, the reader will have gathered much useful material for the reasonable discussion of a subject

[1] *Some Social Aspects of Mental Hygiene.* Edited by Frankwood E. Williams, M.D. London: P. S. King and Son, Ltd.; Philadelphia: The American Academy of Political and Social Science. 1930. (6½ × 9½, pp. iv + 214. Paper cover, 1 dollar; cloth, 1.25 dollars.)

which is rapidly ripening for appropriate action in this country. Educationally and medically, the other article by Dr. Doll above referred to, together with that by Dr. Hollingworth, will be found worthy of serious consideration. They draw attention to some rather neglected aspects of special education, and point the need, in this regard, for making provision for the specially gifted child, for the dull child with compensatory abilities, as well as for the feeble-minded child. Dr. Hollingworth's analysis of the position of the child of 8 or 10 years of age with an intelligence quotient of over 140 is largely new, and carries with it practical lessons both for the teacher and for the doctor. Dr. Doll's statement of the aims of education is particularly clear and suggestive. The two more general articles by Dr. Williams and Dr. Russell on the meaning and position of mental hygiene are to a considerable extent complementary. Together they give an admirable and thought-provoking picture of the way in which the medical profession, psychiatrists in particular, have come to have a much wider view of their sphere of work and a different conception of what "prevention" or "hygiene" means and involves. They describe not merely how the social worker has become of paramount importance to the physician and psychiatrist, but how the doctor himself has necessarily become a worker in the social field, with special qualifications for leadership therein. They emphasize, too, that attention to emotional health is of paramount importance even in a large proportion of those cases in which physical symptoms are manifest; and that therefore it is to emotional training, control, and regulation in childhood that attention may most usefully be directed.

WELFARE OF THE BLIND IN SCOTLAND.

THE Department of Health for Scotland has issued a circular[1] to the local authorities of Scotland regarding the altered arrangements for the welfare of the blind consequent upon the passing of the Local Government (Scotland) Act of 1929. It is pointed out that the local authorities have now considerable experience in the administration of matters affecting the blind, but that certain modification will be needed in the schemes provided under Section 2 of the Blind Persons Act of 1920. The services include the provision of domiciliary assistance of necessitous blind persons, the provision of employment, assistance in setting up in a profession or business, the maintenance of a register of blind persons, the medical certification of the blind, and the granting of assistance towards services of a national character. New arrangements should be made with voluntary agencies. These have in the past received grants from the central authority; now they will receive them from the local authorities through the block grants which the latter receive. The contributions should include amounts equal to those paid, or which should have been paid, by the local authorities direct in the standard year *plus* any additional amounts agreed in respect of new developments. It is noted that there may not be sufficient accommodation in workshops for all the trained blind, so that home workers, schemes such as has been so successful in England, are suggested as a useful form of development. These schemes provide for the care, assistance, and supervision of blind persons employed in occupations usually practised in workshops, and provision is made for the augmentation of earnings. Experience shows that the types of occupation might be extended. For the future the register of the blind will not be kept centrally, each local authority must keep one for its own area. Emphasis is laid on the necessity for the proper keeping of these registers, and for co-operating closely with the voluntary agencies in this work. The circular quotes an extract from the report of the Advisory Committee, and "the Department concur in the view." The proper certification of blind persons is all-important, and while, as a rule, voluntary agencies are unwilling to admit persons to their rolls who have not been certified as blind by an ophthalmic surgeon or a medical practitioner, the arrangements of the associations for certification are not uniformly satisfactory. We are strongly of *opinion that every case should be certified* by an ophthalmic surgeon; and, now that local authorities are to bear full financial responsibility for the services of the associations, they should, in our view, satisfy themselves that proper arrangements exist. Where these do not, they should, financially or otherwise, give every assistance to the associations to secure the necessary improvement in their arrangements. Special note is made of the need for a close co-operation between the committee of the local council charged with the general welfare of the blind and the education committee. It is particularly desirable that delays should not occur in making the necessary arrangements for cases that should be afforded technical education. In an appendix there is set out a "Revised Model Scheme" suggested for adoption by local authorities.

SCIENTIFIC EXAMINATION OF PROJECTILES.

ANOTHER volume has been added to the series of Notable British Trials, dealing with the trial of Browne and Kennedy for the murder of Police-constable Gutteridge.[1] The editor, Mr. Teignmouth Shore, remarks that "To the student of crime this case presents little of interest," but as a matter of fact there are several points of interest from the medico-legal, psychological, and legal aspects. It will be remembered that the murdered man met his death on the night of September 27th, 1927, having been shot twice through the left side of the face and also through each eye. A motor car bearing signs of blood staining was found abandoned on the following day, and in the car an empty 0.455 revolver cartridge was picked up. On January 20th, 1928, Browne was arrested for stealing a Vauxhall car, and when his premises were searched a Webley revolver and service ammunition similar to that used in the Gutteridge murder were found. Kennedy was arrested five days later at Liverpool. In a case such as this the police must have been aware that the murder was committed by a motor-car thief and from the fact that he was armed probably a person who had been in their hands before. As a motor thief must have a garage and workshop a very close watch was no doubt kept on all such premises in the metropolitan area. Whether the arrest of this particular criminal was due to chance does not transpire, but apparently the inspector in charge of the case had no suspicion that Browne was concerned in the Gutteridge case until he had taken his second statement. First, then, by happy chance one of the empty cartridge cases from the revolver fell into the car; secondly, by a strange coincidence, the murderer came into the hands of the police; and, thirdly, this person had foolishly kept the revolver from which the shot had been fired. It appears, however, that there was no direct evidence that could definitely connect the accused persons with the crime. There was no evidence as to their movements on that particular night. The conviction of the accused therefore depended entirely on the evidence that the cartridge case found in the abandoned car was fired from the revolver which was seized in the possession of Browne. This fact was conclusively proved by the experts called for the Crown, who demonstrated that the file marks and other tool marks on the breech shield of Browne's Webley revolver were impressed detail for detail on the copper cap of the cartridge case. This was the first

[1] *Trial of Frederick Guy Browne and William Henry Kennedy.* Edited by W. Teignmouth Shore. Notable British Trials. Edinburgh and London: W. Hodge and Co., Ltd. 1930. (Demy 8vo, pp. x + 218; 16 plates. 10s. 6d. net.)

occasion upon which such scientific examination of projectiles had been made use of in this country, although it has been in use in criminal investigations for many years elsewhere. We have on more than one occasion drawn attention in these pages to the value of such scientific examination. In the Gutteridge case this evidence showed that Browne's Webley revolver had been used for the murder, but it did not necessarily show that Browne had used it, although the medical evidence of the direction of fire indicated that the driver of the vehicle was the person who shot Gutteridge, and it was generally assumed, though not proved, that Browne was driving. In this regard the examination of the cartridge case for finger-prints might have been invaluable. The finger-prints of the person who charged the weapon and possibly of the one who emptied the chambers might well have been discovered on the empty case. We notice, however, that the constable who saw the cartridge picked it up, apparently without any precautions, handed it to the sergeant, who handed it to the inspector, who in turn handed it on to the chief inspector. After such handling the chance of finding finger-prints must have been negligible. A further item which calls for comment is the fact that although the bloodstain on the car was observed on September 27th, 1927, it was not until February 8th, 1928, that it was sent for examination to see if it were human blood. This blood and its freshness or otherwise might have been material evidence, and it should have been examined immediately. We might also draw attention to the fact that no examination of the powder stains on the victim were made, although evidence was given by one of the experts that one wound was due to a cartridge loaded with black powder and another due to cordite. The opinion of this expert was based on the photograph taken at the time, and is therefore of no particular value. It is surely not too much to expect of the police to satisfy themselves on these points when a chemical examination could yield decisive results. The attitude of mind of these two men is an interesting psychological study. If the deliberate shooting of a fellow being to evade possible arrest for theft indicates a contempt for human life then what can we think of the sub-sequent act of discharging two more shots into the eyes of the dying man? The life-history of Browne shows that from childhood he was anti-social in his outlook, and was contemptuous of authority. He had five convictions to his credit from 1911 to 1927 for various forms of theft, burglary, and fraud, and two further convictions for discharging firearms. These were those which were discovered, and we must assume that they represent only a small percentage of the actual crimes committed. For example, from October, 1927, to January, 1928, when he was arrested, he was concerned in eight different affairs of burglary and theft. The other man, Kennedy, had also a history of crime, but in his case there were six instances of indecent exposure, and with this history it is rather remarkable that some attempt was not made with the special defence of mental defect.

OPHTHALMIC HOSPITAL IN JERUSALEM

THE Order of the Hospital of St. John of Jerusalem maintains in Palestine an ophthalmic hospital. In the thirty-eighth report, which covers the year 1929, the warden, Lieut.-Colonel J. C. Strathearn, attributes a fall in attendances by patients mainly to the riots which occurred last year. The fellahin found it safer to stay indoors, and the total attendances fell from 94,832 in 1928 to 63,134 in the year under review, but there was a curious increase in the attendance of town-men from Jerusalem, where private specialists are mostly Jews. In the fervour of boycotting the Jews the Arabs flocked to the hospital, but it is regrettable to learn that the free-will offerings of several hundred better-class Arabs did not amount to £1. Notwithstanding the riots the number of new patients examined in the hospital during the year exceeded 15,000; and of these 13 per cent. were blind in one or both eyes. Most of the blindness could be traced to attacks of acute conjunctivitis, which is endemic in Palestine and is subject to epidemic exacerbations in the hot season. To treat this disease an annexe to the hospital was being built, but work was stopped by the municipality owing to the discovery that the "permit to build" had not been officially sanctioned. This permit may take months to procure since it has to be stamped by as many as twelve different individuals. Owing to recent epidemics of acute conjunctivitis the incidence of trachoma has risen, and last year this disease accounted for 92 per cent. of the new cases seen. In connexion with the hospital there is a "clinic scheme", and 14,000 additional patients were seen at six provincial centres. Here also the riots were a disturbing factor, and the decrease in trachoma operations suggested that the political disturbance had distracted the attention of the fellahin even from this painful and disabling malady. Further extension of the hospital is contemplated in view of the pressure on its accommodation in more normal years.

PATHOLOGICAL RESEARCH IN LEEDS.

IN the annual report for 1929 of the department of pathology and bacteriology of the University of Leeds Professors M. J. Stewart and J. W. McLeod describe some of the researches which have been conducted there. Among these is mentioned the continuation of experimental work on pulmonary asbestosis, in which the "peculiar bodies" which occur in the lungs of asbestos workers have been successfully reproduced in guinea-pigs by inoculating them subcutaneously with asbestos dust. A series of experiments is now in progress to elucidate the changes in the lungs in this disease. Clinical investigations from various points of view are also being made in pulmonary asbestosis. On behalf of the Yorkshire Council of the British Empire Cancer Campaign a study of the iodine content of the blood of patients suffering from cancer has been made, as a result of which it has been found that there is no constant change in this respect. Dr. Polson has examined the distribution of iron following the intravenous injection of colloid preparations into splenectomized rabbits; he is also continuing his work on other aspects of iron storage in this animal, including the varieties of damage inflicted on the liver. Latent tuberculosis in the tracheo-bronchial lymphatic glands has been studied, and a report is being prepared for publication. Tubercle bacilli of the human type were recovered from apparently normal glands in seven out of 109 cases, but in three of these a tuberculous lesion was demonstrated microscopically. With the aid of a grant from the Yorkshire Council of the British Empire Cancer Campaign a large series of cases of cancer of the skin are being investigated from the point of view of etiology. Progress has been made in obtaining a more accurate method of diagnosing gonorrhœa in female patients. Dr. R. D. Passey, professor of experimental pathology and director of cancer research, reports that further evidence has been accumulated in favour of the view that the onset of epithelial proliferation is regulated by the same principles of physical chemistry as govern the precipitation of negatively charged colloids. Certain other considerations indicate the possibility that precipitation of the colloids of the cell membrane is an essential phase in the sequence of changes which culminate in cell division. Other details of cancer research in connexion with Leeds University were mentioned in the annual report of the British Empire Cancer Campaign. Dr. Harold Channon and Mr. Collinson, who have been studying the blood fat content, have made the important observation that liquid paraffin is capable of being absorbed after ingestion by the mouth.

HEALTH OF THE UNITED STATES ARMY.

The annual report of the Surgeon-General of the United States Army for 1929 contains highly condensed information on the health of an army of 134,000 men—white, coloured, Filipinos, and Porto Ricans. The chief disabilities leading to retirement among officers were tuberculosis, arterio-sclerosis, and osteo-arthritis. The leading causes of discharge among the enlisted personnel were dementia præcox, mental deficiency, and "constitutional psychopathic state." But the admission rates for enlisted personnel varied greatly according to race and country. Thus the Filipinos headed the list in tuberculosis, while in alcoholism and venereal disease they were easily at the bottom, with the Porto Ricans not far above them. Both these races suffered heavily from malaria. The relative freedom of the Filipino from venereal disease is explained by his being generally a married man, accompanied by his family, and also by reason of his habits of sobriety. The table in the report showing the admission rates for alcoholism in the United States Army gives statistics from 1903 to 1928. Until 1910 the rate was between 21 and 27 per 1,000 officers and men; 1907 being the "wettest" year. In 1914 the rate had fallen to 13 per 1,000. In 1918 it was less than 1; but had risen to 7 in 1920, and has remained about the same ever since, being 7.6 for 1928. Apparently, however, when white troops get out of the States to a station like the Philippine Islands the rate jumps up again to the 1911–12 level of 17 per 1,000, nearly double the rate for white troops in the United States—8.79. On the face of it this Table 91 should be an interesting study for "wet" and "dry" politicians. In the figures in the report which illustrate the discharge rates for nervous and mental diseases, differently printed lines representing side by side the rates for 1911–16 and 1923–28, show that there has been a great increase in the incidence of mental disorder in white enlisted men, the rate of discharge from this cause having risen from 2.18 to 6.73 per 1,000.

THE LÜBECK DISASTER.

A further stage has been reached in the investigation of the cause of the deaths which occurred at Lübeck in June following the administration of certain B.C.G. cultures to infants. Mention was made in the *Journal* of July 26th (p. 152) of a report by Professor Bruno Lange incriminating the Lubeck Hospital in this connexion. We have now received a letter from Professor Calmette pointing out that the experts appointed by the German public health authorities and the Minister of the Interior have officially declared that the disaster was not caused by the B.C.G., but was due to an accidental contamination of the vaccine with virulent human tubercle bacilli, which occurred in the laboratory of that hospital. Professor Calmette adds that no responsibility can therefore be attached to the Pasteur Institute, nor to those who have recommended this method of treatment, which has now been employed in vaccinating thousands of children all over the world.

PROFESSOR ALLVAR GULLSTRAND.

Ophthalmology and physical science have lost a great worker by the death of Professor Allvar Gullstrand; few men of recent years have done so much work in elucidating the intricate problems of the optics of the human eye. Born at Landskrona, Sweden, in 1862, he was the son of a physician; he studied medicine at the universities of Upsala, Vienna, and Stockholm, and graduated at the last-named university in 1890. At the early age of 32 he was appointed professor of ophthalmology at Stockholm, and held this office from 1894 until 1913, when he became professor of physiological and physical optics, continuing in this post until 1927. While working at ophthalmology he completed some notable research, but in later years devoted himself almost entirely to what might be termed pure physics in his special branch of optics. In 1911 he was awarded the Nobel prize for medicine "for work on the diffraction of light by lenses as applied to the eye," and other honours were paid to him in recognition of his achievements; thus he received honorary degrees in science at Dublin, and in philosophy at Upsala and Jena, and was elected an honorary member of the Ophthalmological Society of the United Kingdom. His work in physical optics may be counted the more remarkable since his training was that of a medical student, and principally related to clinical medicine. At first his practice followed these lines in ophthalmology, but he early began to question the generally accepted views on the passage of light through the refracting media of the eye. He showed that the simple and somewhat crude conception of the refraction of the eye (based upon the conception that its media might be represented by a homogeneous medium, much like a glass lens system) was wholly incorrect, and gave but a poor idea of the complication of the media of the eye, and of their beautiful, even exquisite, adaptation to their peculiar purpose. His chief publications were: *General Theory of Monochromatic Aberration and its Consequences in Ophthalmology*; *Real Optical Images*; *Optical Images in Heterogeneous Media and the Dioptric of the Human Crystalline Lens*; *Studies in Dioptrical Methods of the Human Eye*; *General System of Optical Images*; *Aspherical Planes in Optical Instruments*; and *The Secondary and Tertiary Laws of the Optical System*. He was a singularly skilful and accurate experimental worker, and devised many instruments of remarkable precision, some of which have passed into the everyday use of ophthalmologists. Further, he could explain lucidly the intricate problems with which he dealt, and his charm of manner and patience made his demonstrations amazingly attractive.

MEMORIAL TO MARGARET MACDOWALL.

The death of Miss Margaret Macdowall in the early part of this year drew attention to the pioneer work on behalf of mentally deficient children which she had been conducting, first in Ealing, and later at Burgess Hill. References to this by Sir Maurice Craig and Dr. A. F. Tredgold appeared in the *British Medical Journal* of March 22nd (p. 569) and April 5th (p. 670). An appeal is now being made for donations towards a memorial which, it is thought, might well take the form of a new edition of her book, *Simple Beginnings in the Training of Mentally Deficient Children*. This book was published in 1919, and was warmly commended that year in the *Journal* of July 5th (p. 13); it is still in constant demand, but it has been out of print for some time, and the estimated cost of a new edition with some biographical notes added would be about £100. If, as is hoped, the response to the appeal brings in a substantial sum, it is proposed to use the balance and the proceeds from the sale of the book to create a fund for making grants in aid of the training of educated girls to work among mentally deficient children. The appeal, which will close on October 31st, is supported by Sir Maurice Craig and Dr. A. F. Tredgold, among others; donations should be sent to the treasurer, Mr. Harold Moreland, Cherrycroft, Gerrards Cross, Bucks.

The Council of the Royal College of Physicians of London announces in our advertisement columns this week that it is prepared to receive applications for the post of Milroy lecturer for 1932. The course consists of three lectures to be given in February or March. A copy of Dr. Milroy's suggestions, together with information as to the emoluments, may be obtained from the Registrar, to whom applications, containing a statement of the division of the subject selected by the candidate, should be sent by September 30th, 1930.

THE ELEVENTH INTERNATIONAL VETERINARY CONGRESS.

ABOUT 1,800 delegates from all the civilized countries of the world attended the Eleventh International Veterinary Congress, which was opened in London on August 4th by the Earl of Harewood. In declaring the congress open Lord Harewood said he did so with mingled feelings of pride and shame: pride in the fineness of British stock, and shame at the state to which the London Veterinary College buildings had fallen. The purpose of the congress was the dissemination of knowledge to veterinarians, to the public, and to Governments. The first congress had been called to consider important contagious diseases, such as cattle plague, which had now been brought under control. Interest was still taken, however, in foot-and-mouth disease, and he hoped that soon the present mode of control would be replaced by a more scientific method. Bovine tuberculosis was another disease requiring attention, and he was sure that in its eradication the veterinarian would receive the cordial support and encouragement of the medical profession. In addition to the public health and economic aspects of veterinary science, some attention should be paid to the humanitarian point of view, an aspect which would always commend the fullest public support.

Sir JOHN MCFADYEAN, M.B., P.R.C.V.S., was appointed president of the congress. In his address he sketched the history of the various international congresses from their beginning in 1863, when John Gamgee organized the first congress, which was held in Hamburg. The speaker remarked that, although the honour of this belonged to an Englishman, it was surprising to notice that apart from himself only one other Englishman was numbered among the 101 members. The attendances had gradually increased, and the proceedings had become better organized as time went on. The tenth congress had assembled in London just before the outbreak of war, in consequence of which it came to an untimely end. The present congress had broken all records in respect of the numbers present and of the subjects presented for discussion.

Variola in Animals.

In a paper read in the afternoon of August 4th, Mr. R. E. GLOVER (Cambridge) discussed the virus of contagious pustular dermatitis of sheep and goats, which he considered to be one of the vaccina-variola group. He said that the disease was found in various parts of Great Britain, and apparently only a single strain of the virus existed here. Some workers thought that variola, vaccina, and sheep-pox represented a single disease, adapted perhaps to different animals, and reacting a little differently according to the species. Others, while admitting a common origin of the variolous diseases, regarded them now as specific for the species which they affected, and incapable of conversion the one into the other. A similar conflict of opinion had existed about the relationship of vaccina, horse-pox, and the equine contagious pustular stomatitis. Glover considered that the question was still *sub judice*, while inclining to the view that dermatitis and vaccina were distinct. The condition known as malignant aphtha in ewes, however, was due to the dermatitis virus.

Dr. BRIDRÉ (Pasteur Institute, Paris) reviewed the various variolas in animals. He stated that vaccina occurred naturally in the cow, horse, camel, goat, and pig; the variolas of the goat, pig, and sheep were, however, specific to these animals. In the goat, the disease was benign; in young pigs and sheep it was serious. The virus was always present in the specific lesions, and was capable of passing through certain filters. The virulence might be reduced by passage to less susceptible animals; during outbreaks the virulence was sometimes suddenly exalted. Natural immunity was rare, and when it occurred it might be characteristic of a particular breed; thus Breton sheep were resistant to sheep-pox. Each of the variolas immunized against itself, while vaccina immunized against human variola, and vice versa. The acquired immunity was durable, but not of indefinite duration.

Dr. H. S. PFENKEL (Utrecht) discussed the so-called "natural" cow-pox, which was not uncommon in Holland. It had been impossible to demonstrate any relation between this disease and vaccinated persons, but the speaker believed that most cases were due to infections from newly vaccinated men. However, other possible sources might be found in horse-pox and fowl-pox. The whole problem, he added, was very complicated, and had an important public health aspect. The milking personnel might be easily infected from diseased nipples. Cow-pox was common, and men were so often infected that it had become an industrial disease. In Jenner's time this was a fortunate circumstance, but nowadays infected persons risked an unnecessary, disagreeable, secondary infection. This risk could be avoided by vaccinating the cow in a suitable place and during its non-milking period.

Control of Anthrax.

The control of the dissemination of anthrax by animal products was the subject of a sectional discussion. Dr. F. FISCHOEDER (Warsaw), who opened it, pointed out that countries importing skins could demand official certificates: (1) that the animals had been slaughtered in slaughter-houses under veterinary supervision; (2) that the animals had been inspected both before and after slaughter, and found free from infectious diseases—especially anthrax: and (3) that the hides had not come into contact with animals suspected of anthrax, or with objects capable of acting as carriers of the disease. Skins not accompanied by such a certificate should be excluded, or their importation made conditional upon the result of a thorough examination. A similar examination should be insisted upon in cases—even when accompanied by certificates—in which the veterinary inspection services were not regarded as satisfactory. Ascoli's technique might be used with advantage for the examination of hides, and skins which gave negative results might be admitted, a positive result, however, was not proof of the presence of anthrax, and cultivation and inoculation must be resorted to for the demonstration of the organisms.

Professor MUSSEMEIER (Berlin) stated that, while in animals anthrax was for the most part of alimentary origin, in man it was usually respiratory or cutaneous. Animal infection was usually traceable to the careless disposal of infected carcasses, and regulations had done much to reduce its incidence in Germany. The main risk in Germany arose from imported hides, bones, and foodstuffs. The statistics of anthrax infection in man, cattle, and pigs showed a curve parallel with that of the importation of hides and foodstuffs. Accordingly, the most strenuous efforts should be made by exporting countries to dispose of anthrax-infected carcasses in the safest manner. If this was not done, foreign bones and meat meals must be sterilized on arrival. The most serious danger was attached to dried hides, and there was no known method of rendering them safe without causing damage to them. The speaker recommended Ascoli's test in the case of hides, by either the exporting or the importing country.

Foot-and-Mouth Disease.

Professor J. LIGNIÈRES (Buenos Ayres), opening a discussion on foot-and-mouth disease on Tuesday morning, August 5th, reported that he had been able to isolate two types in the Argentine and Uruguay. The virus dried under favourable conditions might retain its vitality and virulence for some months, and so give rise to spontaneous outbreaks. The speaker considered that this was the explanation of some of the British outbreaks, rather than the Argentine meat blamed by some people. It was necessary, therefore, to insist on rigid disinfection of places, vehicles, and everything coming into contact with infected animals. The best disinfectant for efficacy, rapidity, cheapness, and absence of injurious action was sodium hydrate used in a 1 per cent solution for animals, and 2 per cent for inanimate objects. Professor Lignières added that he had devised a new method of vaccination against the disease, which was very simple in use. Details were withheld pending a thorough test of the method.

Sir JOHN MCFADYEAN, chairman of the organizing committee, doubted the advisability of conceding the request

of Professor Lignières for an international commission to be called into being to examine the efficacy of the new remedy, since its composition was not to be disclosed until subsequently. It might well be tried out first in the Argentine or some similar country. On being put to the vote the proposal of Professor Lignières was rejected by a large majority.

Dr. W. H. ANDREWS said that he accepted as proved the plurality of virus strains. In addition to the three generally recognized strains, however (O, A, and C), it appeared that there were also other immunological types which were not intermediate, but distinct. Two such strains had been recovered from outbreaks in England. Of 40 strains in Britain, 37 proved to be O strains, and there was no doubt that this was the predominant form in Europe. This plurality of virus types rendered prophylaxis much more complex, difficult, and costly. It had been proved possible to immunize animals simultaneously against more than one type, but there was still uncertainty as to the number of types existing. A characteristic attack practically always left an animal completely resistant to the homologous type of virus. The immune animal first lost its local or tissue immunity (in cattle in about seven months), but the humoral immunity was more lasting—on an average between one and two years. A few experiments at Pirbright suggested that humoral immunity would protect cattle against natural infection. Probably any method of active immunization would involve some risk in spreading the disease, but special measures, such as the creation of a zone of passively immunized animals, might render such methods of very great value to many countries.

Professor WALDMANN (Germany) stated that investigations had been greatly extended during the past decade. The virus had not yet been isolated, but filtration and ultra-filtration experiments indicated that its size was about 3 μ. There were three distinct strains which did not immunize against one another, and also variants which were correlated to the type they most closely resembled. The diseased animal and its stall constituted a serious source of danger. Infected animals excreted the virus in the milk, urine, faeces, and saliva for ten days after becoming ill; it persisted longest in the saliva. Temperatures below 10° C. conserved it; those above 30° C. were harmful; and moist heat over 50° C. killed it rapidly. It was very susceptible to putrefaction and sunlight. Artificial drying of the vesicular contents prolonged the life of the virus, and epithelium from the vesicles was far more resistant than vesicular fluid against all external influences. Active immunization was still unsatisfactory, but protection for ten days could be obtained with hyper-immune serum, which should be polyvalent. This method, however, was only of value for animals exposed to infection for a brief period, or during outbreaks on a farm.

Protective Inoculation against Rabies.

Professor A. AUJESKY (Budapest) expressed the belief that protective inoculation might be used after infection to save animals that had been infected, or, particularly in dogs, to prevent the spread of the disease. Any method employed after infection had occurred must establish immunity within a short time, by simple means, and with few injections at small cost; it must also be free from the danger of producing the disease itself or other undesirable sequels. The methods in use which satisfied these conditions were mostly those which made use of fixed virus attenuated with carbolic acid or by ether, and which required at most six or seven injections; a simplified "dilution method" was employed in Hungary. Animals in an advanced state of pregnancy withstood these methods well, and milk from inoculated animals might safely be sold. While inoculation should be early, it was well to remember that the incubation period was often several months, and therefore several weeks might elapse between infection and inoculation. Protective inoculation of dogs could only be considered as a support to existing regulations, and it did not render them superfluous. Regulations alone were sufficient to control rabies in a country where the disease did not normally exist, but where it was widespread protective inoculation should be used to assist the regulations. The Japanese method, with a fixed virus, carefully conducted, produced a good degree of immunity with a single injection; so also did Miessner's vaccine. Other methods should not be used in practice. Inoculation of infected dogs was best avoided as a rule; it should be limited to valuable animals in places where the law did not insist upon the destruction of dogs suffering from rabies. Cats should not be immunized against the disease.

Professor FINZI (Milan) considered that the efficacy of the campaign against rabies was dependent upon the rigid application of well-recognized sanitary police regulations. But where the disease existed these regulations should be supplemented by the compulsory curative and protective vaccination of dogs. The glycero-carbolized vaccines served this purpose. Curative vaccination was always recommended when the owner could not be compelled to have the animal destroyed. Fixed virus of canine origin could be used instead of fixed virus from rabbits when considerable quantities of vaccine were required. Owing to the small amount of nerve substance necessary the protective inoculation of dogs could be undertaken annually. The curative vaccination of the large herbivora against rabies should be considered as an economic question, and not intimately connected with the special problem of rabies prevention. Professor Finzi added that the antirabic vaccination of dogs should be made a compulsory addition to the enforcement of the sanitary police laws.

Vaccination Against Tuberculosis.

Professor ASCOLI (Milan) recorded his conclusion that the B.C.G. vaccine against bovine tuberculosis was innocuous; in a large series of experiments there had never developed at the site of inoculation a reaction lesion giving rise to tuberculous infection. The mistaken idea that the vaccine was virulent was due to the fact that at the place of inoculation there subsequently developed a regressive tubercle. His own experiments had afforded confirmation that inoculation experiments up to the fortieth passage of a virulent bovine strain on media containing bile revealed a gradual attenuation, as was shown by progressive limitation of the tuberculous infection. He believed that discordance between experiment and experience might be due to infections with the actino bacillus. A sufficiently large dose of the B.C.G. vaccine by mouth in the first few days after birth would confer protection upon calves against natural infection.

Dr. GUÉRIN (Paris) pointed out that it was a mistake to think that active vaccination against tuberculosis was of itself sufficient to ensure protection. Initial sanitary precautions were essential both in cattle and in men. Since it was only the presence of living tubercle bacilli in the body which produced resistance, the first organism to gain access must be a harmless but efficacious bacillus of the B.C.G. type. Prevention, therefore, must consist of rigid isolation immediately after birth, feeding on tubercle-free milk, and inoculation with B.C.G. If an animal in an allergic state resulting from the vaccine was subjected to superinfection with tubercle bacilli, there should be a balance between the number of infecting organisms and the number capable of being eliminated normally by the body; if the number was larger actual tuberculosis might result. The veterinary committee on B.C.G. instituted by the League of Nations in 1928 decided that vaccinated and control animals should continue to live the ordinary life on the farm, and should not be subjected to any artificial contagion. Dr. Guérin considered that tests on small laboratory animals with the B.C.G. vaccine were not conclusive, since initial hygienic measures were essential and ignorance of protective measures for small animals led to bad results. The more closely that investigators adhered to the conditions which were known to be essential, the more favourable were the conclusions reached as regards the efficacy of the vaccine. The speaker pointed out that those who desired to fight bovine tuberculosis must follow two rules. The B.C.G. method could be applied on all farms infected with tuberculosis where it was the custom to raise young animals to replace the old ones. These farms must be provided with a small isolation stable, carefully disinfected and kept in proper condition constantly, in which calves were put immediately after birth and prior to dressing the navel.

Mr. E. A. WATSON (Canada) reported a series of experiments with the B.C.G. vaccine in Canada. In general he had found no striking difference between animals vaccinated with B.C.G. or with virulent bacilli, and unvaccinated controls so far as the lesions were concerned. The B.C.G. vaccine might retard the development of infection, but this was a transient phenomenon. A comparative study over five to six years did not substantiate the claims made for B.C.G. vaccination as an efficient means of protection against bovine tuberculosis. The speaker considered that its use in Canada was contraindicated, because the incidence of the disease and the conditions which prevailed were favourable to the success of drastic methods aiming at the destruction of the sources of infection.

Deficiency Diseases.

Professors J. MARFK and O. WELLMANN (Budapest), reviewing the deficiency diseases which occurred spontaneously in domestic animals, defined five groups of avitaminosis. They pointed out, however, that attention must be paid to diseases of metabolism, and other factors in the food must be considered in conjunction with lack of vitamins. Diseases due to lack of vitamin A (antixerophthalmic) were rare in domestic animals, although nutritional diphtheria in birds was a possible example. Polyneuritis in poultry was due to lack of vitamin B (antineuritic), and beri-beri-like conditions had been observed in dogs and rabbits. C-avitaminosis caused scurvy, and various conditions had been attributed to lack of this vitamin in pigs and other animals. Rickets and osteomalacia were not essentially due to lack of vitamin D, but depended also on a deficiency of calcium or phosphoric acid. Rickets in animals corresponded with late rickets in man, the difference between this condition and infantile rickets lying in the more advanced stage of bone development at the time the disease appeared in animals and the far greater mechanical involvement of the skeleton. These differences, especially the fibrosis of the marrow, the excessive exaggerated formation and osteoclastic resorption of bone tissue, were characteristic of animal rickets, and did not permit of their separation from true rickets and their classification as fibrous osteitis.

Professor V. STANG (Berlin) thought that the importance of the individual vitamins was frequently overestimated. The conditions were not such that the presence or absence of a vitamin alone determined health or sickness, the results obtained in the treatment of deficiency diseases show that climate, soil, condition, and food were of greater importance. Diseases due to lack of vitamin A were rare in animals, and it was interesting to note that the cow could store up this vitamin, and secrete it in the milk, after a diet that had been poor in it for three months. Cattle also produced vitamin B in their bodies, and it was always present in milk. Cattle had either no need of vitamin C or else formed it in their own bodies—a point of importance in the production of milk for children. Vitamin D was important, but rickets was caused not only by its deficiency, but also by insufficiency of minerals. Unfortunately calcium and phosphorus metabolism had not yet been investigated with sufficient thoroughness to provide figures indicating the needs of the various species of animals, and the best proportions of the two substances. It was known, however, that there were marked differences between the mineral metabolism in growing animals, pregnant animals, and milk-producing animals. The type of mineral metabolism, according to recent investigations, varied during the course of lactation—a point of importance in milk production.

Standardization of Biological Products.

Dr. A. EICHHORN (New York), after reviewing the serums, vaccines, and diagnostic agents in common use, drew attention to the urgent need for their uniform standardization, and suggested the creation of an international committee for the purpose of collecting data and organizing the work. This committee would be authorized to have active work conducted in various institutions, would establish central distribution places for the cultures, toxins, and serums, would publish procedures of standard methods of production as well as of application, would prescribe the technique of the application of the various biological tests, and would furnish information for the uniform interpretation of the results.

Dr. G. FLEISCHER (Berne) agreed that standardization was necessary, but suggested that the Commission on Standardization of the League of Nations should be the authority.

Dr. J. R. MOHLER (Washington) thought that each nation should take steps to provide regulations controlling the production and distribution of viruses, and serums, and that such control should be under the veterinary authority of the State.

Meat Inspection.

On Friday morning, August 8th, a discussion was held on veterinary science in relation to public health, with special reference to the production and distribution of meat and milk.

Professor R. VON OSTERTAG (Stuttgart) said that the duties of veterinary medicine were not limited to the animal, there were far more important relationships with public health administration on account of the occurrence in animals of diseases which were transmissible to man. The production and sale of meat were important duties of veterinary science for the prevention of infection of human beings, as well as for other reasons. Meat production would be simple if agriculturists had only healthy animals to deal with. The most important of the diseases in live-stock were those which rendered meat production uncertain. Control of these diseases must be effected by thorough protection against the introduction of diseases from abroad, and suitable regulations for the prompt suppression of outbreaks within the country. Already cattle plague, pleuro-pneumonia, and sheep-pox were controlled, and anthrax and black-quarter were being brought under control. Other diseases of the greatest importance were swine fever, tuberculosis, and foot-and-mouth disease—the latter reducing the value of every infected animal by at least 50 to 100 gold marks. In Great Britain and the United States foot-and-mouth disease had been stamped out by slaughter; elsewhere, important progress had been made by the use of the Loeffler-Waldmann serum. Where tuberculosis was rare, its control had been effected by the use of serum, but where it was extensive, as in Germany, good results had been obtained by fighting the "open," dangerous forms only. Apart from regulations, veterinary medicine had important connexions with the production of meat, through the hygienic control of diseases associated with breeding, with animal parasites, and with avitaminosis. It had important duties in relation to basic rations, and to the determination of the most suitable kinds, breeds, and ages of animals for meat production. The supervision of the sale of meat was a purely veterinary duty, it dealt with the detection of animal diseases transmissible by ingestion to man, or which rendered the meat unsuitable in some other way for human consumption. The supervision of the sale of meat was associated with the veterinary inspection of animals for slaughter and of meat, and also with the veterinary control of foodstuffs. This formed the first line of defence against the dangerous animal parasites—anthrax, rabies, glanders, undulant fever, tuberculosis, and the diseases causing meat poisoning. The uniform method of examining animals and meat was ensured by regulations regarding ante- and post-mortem examination, transport of animals, and erection of public slaughterhouses, at least in the larger communities. The examination of animals and meat must be supplemented by the veterinary control of foodstuffs—including the detection of unauthorized preservatives and of adulteration—and of game, birds, fish, and amphibia. The remarkable results already obtained in connexion with the control of diseases transmissible to man (particularly the tapeworm and trichina worm) and other diseases, including meat poisoning showed the importance of veterinary control in the meat trade.

Dr. H. C. BERGER (The Hague) pointed out that meat inspection and meat hygiene must be founded on a legal basis. The laws might be carried into effect by the local or central authority, but the inspection must be uniform throughout a country. The supervision should be by Government veterinarians, who might, however, be

assisted by lay inspectors. Good hygienic conditions must be prescribed for all trade establishments handling meat or meat products; condemned meat must be destroyed, being preferably converted into valuable by-products. Public slaughterhouses should be established, and humane slaughter should be obligatory. Imported meat also should be inspected, and some international understanding should be reached.

Dr. H. S. FRENKEL (Utrecht) considered that as a foundation for a meat inspection law, principles based on veterinary science must be chosen; in prescribing these principles, bacteriological examination should be included. By means of this it was possible to promote both hygiene and economy. Ante-mortem inspection as well as post-mortem examination was essential.

Milk Inspection.

Professor R. VON OSTERTAG (Stuttgart) stated that to ensure the supply of a sound, harmless, and satisfactory milk, veterinary inspection was essential. The chief diseases which endangered the milk supply were foot-and-mouth disease, tuberculosis, contagious abortion, and "yellow" (contagious streptococcal mammitis), a disease becoming more and more a source of anxiety in dairies. Veterinary regulations also excluded such diseases as anthrax, rabies, cow-pox, diseases of the paratyphoid-enteritis group, and local udder diseases. The provision of clean milk resulting from the proper construction of cow-houses, attention to cleaning the udder, careful removal of milk from the cow-house, straining, and cooling were all matters of veterinary control.

Mr. A. GOFTON (Edinburgh) reviewed the development of milk legislation in Great Britain. He said that there was no Government veterinary public health service in existence, and that the veterinary officer only entered the sphere of public health in the local administration of towns and county districts. Milk legislation was not uniform. It was not until 1899 that the veterinary surgeon secured a legally recognized place in general milk legislation, and then only in respect of tuberculosis of the udder of cows. In England and Wales the Milk and Dairies (Consolidation) Act provided for the appointment of veterinary officers. Some few counties had appointed whole-time veterinary officers, others had appointed part-time officers; but many had no systematic inspection. In Scotland, a similar Act was in operation, but practically every county had a whole- or part-time officer. The Tuberculosis Order was complementary to the milk Acts, and gave certain powers to slaughter. It was not intended to control the disease, and was essentially a public health measure. The milk Acts were leading to an extensive survey of dairy premises, and to progress in raising the standard of housing for dairy stock. Together with various voluntary influences they had also been productive of improvements in the hygienic collection and distribution of milk. The grading of milk was only partial in its application. There were four grades recognized: "Certified," "Grade A (T.T.)," "Grade A," and "Pasteurized." The first two were the produce of tubercle-free cows. Licensed producers in Scotland were able to maintain the fat standard of 3.5 per cent. required, and most samples were well below the maximum bacterial standards permitted. The most common source of failure was in respect of the coliform test. Progress in the establishment of tubercle-free herds was slow, owing in part to lack of public support; in 1929 there were only 447 licensed tubercle-free herds in Great Britain.

Professor C. F. VAN OIJEN (Utrecht) pointed out that the veterinary surgeon had a dual relationship with milk: in studying and combating animal diseases which rendered the milk unfit for human consumption, and in the advancement of the production of first-grade milk and the study of the technical problems concerning the handling of milk and practical milk control. In really first-class milk *B. coli* should not occur, and there should not be found more than some few thousands of bacteria per cubic centimetre. By the practical sterilization of dairy utensils and cooling of milk under 10° C. milk might be produced on almost any farm possessing fair hygienic conditions. Veterinary surgeons could play an important part in propagating sound ideas about efficient milk production.

At the closing meeting of the congress on Saturday morning a number of resolutions were submitted for general approval. In connexion with foot-and-mouth disease, it was urged that every country should determine the type of virus present in each outbreak. The most effective disinfecting agents were moist heat and sunlight, potassium and sodium hydrate, and formalin. It was considered that the value of passive immunity had been established; its use under favourable circumstances should be encouraged, and all possible efforts should be made to discover an efficient method of active immunization. Owing to the widespread occurrence of bovine contagious abortion, it was recommended that there should be an international scientific investigation under the auspices of the International Bureau for Animal Diseases in Paris. Dealing with the danger of human infection with anthrax from unheated or insufficiently heated animal products, the congress decided that regulations were urgently required to ensure that only raw materials from animals free from anthrax were introduced into trade. If the veterinary regulations of exporting countries were inadequate to ensure this, it was essential that the products should be sterilized or tested as to their bacterial content by the importing countries before general circulation.

It was announced that the next congress would be held in 1934, in the United States, and probably in Boston. The Budapest medal was awarded jointly to Professors Hutyra and Marek of Budapest, the authors of the well-known *Comparative Pathology and Therapeutics of Domestic Animals*. The congress concluded with resolutions of thanks to the British Government, the City of London, and many individuals for their hospitality to delegates, and to the president, Sir John McFadyean; the secretary of the organizing committee, Dr. Fred Bullock; and others for the part they had taken in organizing the congress.

England and Wales.

Retirement of Two London Coroners.

Two London coroners, Mr. H. R. Oswald and Sir Walter Schröder, will retire on October 31st. Mr. Oswald was appointed in 1902 as coroner for the south-eastern district, and in 1919 as coroner for the western district. He has been president of the Coroners' Society of England and Wales, is a barrister-at-law, and prior to his appointment practised at the Central Criminal Court; he is also a doctor of medicine. Sir Walter Schröder was appointed coroner for the central district in 1910. He was first appointed a deputy coroner in 1894, and previous to his appointment as coroner had served for eleven years as deputy in the same district. He has been president and is now honorary secretary of the Coroners' Society, and has constantly been consulted upon important proposals affecting coroners and their duties, particularly in connexion with alterations of the law. The London County Council, in accepting the resignations, states that in carrying out their duties the two coroners have displayed conspicuous zeal and ability, and their relations with the Council have always been of the most cordial nature. An expression of the Council's warm appreciation of their long and faithful service has been conveyed to them.

These two resignations enable the London County Council to proceed with its proposals for the revision of London coroners' districts; particulars of the proposed alterations appeared in the *British Medical Journal* of August 17th, 1929 (p. 322). Instead of seven districts, there will in future be six—namely, the western, central, eastern, northern, southern, and south-eastern. The two coroners for the franchise districts of the Duchy of Lancaster (Clapham and the Savoy) and Westminster have agreed to tender at once their resignations of these districts (which are to be abolished), and will be allocated to two of the new districts. Three of the others will be filled by the remaining three county coroners, leaving one vacancy, for the new northern district; the necessary steps will be taken to fill it. The salary of the coroner for each of the proposed six districts will be £1,700 a year inclusive.

The London County Council has also taken the opportunity to consider the conditions which should be attached to such appointments. Coroners have not in the past been required to pass a medical examination, but in view of the grant of pensions to coroners the Council is of opinion that in future such appointments should be subject to that condition. A definite requirement to give whole-time service will be laid down, and the coroner will be expected henceforth to retire at the age of 65. No person will be accepted as a candidate for the appointment of county coroner unless he has attained the age of 35, and is under 50. He will also be required to provide at his own expense office accommodation and clerical assistance, to defray all other expenses of his office, to exercise his discretion so as to avoid the holding of unnecessary inquests, to hold inquests without juries in suitable cases, and to obviate unnecessary expenditure in the discharge of his duties.

The two coroners now retiring are eligible for pensions from the London County Council—in the case of Mr. Oswald of £900 a year, and in the case of Sir Walter Schroder of £731.

Pathological Laboratory Services in London Council Hospitals.

Consideration has been given by the London County Council to the question of an adequate laboratory service for the general hospitals transferred from the boards of guardians. There is a laboratory at each of the hospitals of the late Metropolitan Asylums Board; in addition, a research and pathological service was instituted in 1926, comprising two group laboratories for the purpose of carrying out advanced work which could not be done at the hospital laboratories. There is also a special laboratory at Belmont, Surrey, where all the diphtheria antitoxin required in the fever hospitals is prepared. In certain of the twenty-seven Poor Law hospitals taken over from the guardians rooms have been fitted for simple pathological work, but in others no accommodation is provided. There are only five reasonably equipped laboratories in these hospitals. In some cases the pathological work is sent out to private laboratories, or to laboratories in the voluntary hospitals. Finally, to complete the laboratory service at present under the control of the London County Council there is a small pathological laboratory at the County Hall for the existing public health and school medical work.

The central public health committee is of the opinion that it may eventually be found necessary to maintain a well-equipped and adequately staffed laboratory in every general hospital providing for the needs of acute cases of illness, and to establish one or more central laboratories to cope with the more difficult and intricate pathological work which requires more expert knowledge and more elaborate equipment. At present and for some time to come, however, a complete scheme is not practicable, but it is considered very desirable that certain arrangements should be made to meet immediate needs and to be of a nature capable of expansion. These arrangements include the provision and equipment of a suitable laboratory at each of the general hospitals for routine pathological work. It is also proposed that five laboratories, one in each of the five areas in which the County of London is divided for the purpose of hospital administration, should be "group laboratories," capable of dealing with more specialized pathological work. The central representative committee of the voluntary hospitals cordially agrees with these views, but suggests that in the formation of the proposed five "group" laboratories advantage should be taken of the facilities afforded by the existing pathological departments of the voluntary hospitals. This suggestion has been carefully considered, but the central public health committee is still of the opinion that the five "group" laboratories should be provided at the council hospitals. The hospitals selected for the purpose are Lambeth Hospital (where there is already a laboratory capable of enlargement), the Archway Hospital (Archway Road, Highgate), Lewisham Hospital, St. Mary Abbots Hospital (Kensington), and Hackney Hospital. At the Hackney Hospital the provision of the laboratory will be included in the extension of the hospital for which arrangements are in hand. In the cases of Lambeth Hospital, the Archway Hospital, and Lewisham Hospital plans showing the arrangements proposed to be made have been approved. Altogether the estimated cost of the necessary structural alterations and adaptations will be about £13,000. The present scheme is stated to be in the nature of a beginning only. Future development will proceed by way of adding to the facilities now to be provided or more probably by increasing the number of "group" laboratories. The staffing of the laboratories is to be the subject of a further report.

St. Chad's Hospital, Birmingham.

In the report of St. Chad's Hospital, Birmingham, for the year ended March 31st, 1930 the committee refers to its fifteen years' practical experience in providing medical and surgical treatment at a moderate inclusive cost. The hospital was established by a small number of Birmingham consultants primarily for the use of those patients who could not afford the heavy expense of a private operation and did not wish to avail themselves of the charitable services of voluntary institutions. In reviewing the administrative and financial difficulties associated with the scheme, the committee states that the problem of reducing the total cost of medical treatment and nursing home accommodation to at least half of the usual charges, while providing the facilities of voluntary hospitals, can only be solved by maintaining a consistently high standard of efficiency—a condition that precludes cheap nursing accommodation. It considers that reduction in this item alone is not only negligible in reducing the total costs, but leads to impaired efficiency in every direction or compels resort to subsidy or charity. Its experience has shown that the only way of satisfying both medical staff and patients is to accept the fact that efficient nursing home accommodation cannot be provided under about one guinea for each day's stay, the main reduction in total costs being obtained by arranging for smaller medical fees and for a fair assessment of the patient's financial position. In this connexion the services of the almoner at St. Chad's Hospital have been increasingly utilized and efforts have been made to deal with each case on its merits. Patients may be referred for assessment to the almoner by members of the hospital staff or by their own doctors whose approval is necessary before admission. Since the issue of the last report the hospital has acquired a supply of radium and a new maternity department has been opened including a labour ward and a nursery. During the year over 900 patients paid inclusive fees which were half the usual cost of treatment. 230 were accepted at the minimum rate. The committee suggests that a simple form of insurance might be provided by an outside body to cover the risk of illness requiring special treatment in a nursing institution or hospital for paying patients.

Records of Health Services.

A circular has been issued by the Ministry of Health referring to the annual returns required in future from local authorities in regard to maternity and child welfare, tuberculosis, and venereal diseases. Further particulars of the administration and progress of these services are stated to be necessary on account of the changes introduced by the Local Government Act 1929, transferring the supervision of the maternity and child welfare work of voluntary associations to local authorities, and Poor Law institutions to county and county borough councils. A separate return must be made of maternity homes and hospitals provided or subsidized by local authorities, and of maternity wards in institutions transferred to county and county borough councils. Returns furnished by local authorities relating to this service are to include the maternity and child welfare work of voluntary associations. In regard to venereal disease annual returns are required from medical officers of treatment centres and from pathological laboratories approved under the Public Health (Venereal Diseases) Regulations, 1916. Besides the customary returns of notifications of tuberculosis, information is required of the accommodation available at the end of the current year for the treatment of this disease in Poor Law institutions belonging to the council (or to the constituent authorities of the joint committee), and in

regard to the extent of residential treatment provided during the year in such institutions for persons chargeable to these bodies. An annual return must also be made by county and county borough councils specifying the amount and nature of the accommodation available for the treatment of the sick in institutions transferred to them, and in general hospitals provided under the Public Health Acts or the Local Government Acts. This return must also indicate as far as possible the use that has been made of the accommodation during the year. Local authorities are requested to furnish the returns referred to above not later than February 28th of the year following the period to which the returns relate. The circular also enumerates a number of returns which the Minister of Health has decided to dispense with in connexion with these services.

Scotland.

National Health Insurance in Scotland.

Mr. William Adamson, Secretary of State for Scotland, delivered an address on August 4th at the ninety-fifth Foresters' Court at Greenock. Mr. A. Marsden, who presided, said that there were often complaints in regard to the burden of social services at the present day, but in the popular enumeration of Britain's economic difficulties health insurance had met with less condemnation than most of the other principal components of this burden, because it had been generally recognized as genuine insurance with nothing of the dole about it, and because it was believed to be solvent, with a good margin to spare. The Secretary of State for Scotland said that the more he reviewed the various problems of the day the more he realized the value of the principles and ideals of friendly societies in the training which they provided for the best type of citizen. He was glad that this society had been able to provide additional benefit in the shape of dental and ophthalmic treatment, and its convalescent home scheme would be watched with interest by the Department of Health. They were watching with anxiety the increased rise in sickness and disablement expenditure which had extended to all the friendly societies, and they could not be content to leave things as they were. The nation was spending £200,000,000 annually on social services, and yet there was the extraordinary phenomenon of an increased number of claims for benefit under the national health insurance scheme. This problem concerned every single citizen, and was one for which no satisfactory explanation had yet been found. In Scotland machinery had been set up to compile statistics with the help of approved societies, showing the amount of sickness attributable to various ailments among men and women; the result would be made available both for doctors and for societies, and also for the guidance of local authorities. This was a kind of experiment, designed to find out not only weakness in the administration, but in order to detect the illnesses which were the common cause of incapacity. The speaker said he would visualize a still greater service than existed to-day, even without legislation, by the exercise of good will, so that a more definite relationship could be obtained with voluntary hospitals and other institutions. The meeting was continued on August 5th, when it was reported that there were now 105 convalescent homes established in various parts of the country for members of this approved society; more than £4,000 had been expended from the voluntary funds in the past year, in addition to a large sum administered under the Health Insurance Act. The results of the health insurance valuations of the society made by the Government actuary were reported; they revealed a gross surplus of £2,700,000, an increase of over £400,000 as compared with the 1922 valuation. At a continuation of the meeting on August 6th, an address given by Miss Ritson, the controller of health insurance pensions for Scotland, was discussed. The speaker had said that during the past two or three years things had not been going well with national health insurance, and the Government actuary had told them bluntly that they were spending more than they could afford. Two outstanding causes of the increase in expenditure had been the increasing number of claims of the short illness category, and an unparalleled call on the funds by married women. The question had been asked whether there was laxity in the administration of benefits, whether doctors were certifying wrongly, whether there was a steady deterioration in the health of the nation, and whether claims made in respect of these illnesses could not be prevented. All concerned should bend their efforts towards answering these questions. Malingering had not been proved, but everyone knew that sometimes just an effort of will was required to produce capability for work, and it might be that the nation was becoming more ready to accept the easy path, or to insist on having the path made easy. A resolution was adopted that medical practitioners should fix the date when a panel patient was next to present himself for consultation, and that this should not be left to the discretion of the patient.

Research at the Royal College of Physicians, Edinburgh.

Sir Robert Philip, who is curator of the laboratory of the Royal College of Physicians of Edinburgh, states in his annual report for 1929 that the group of research workers there has been well maintained, and that the results of their labours have been gratifying. The Freeland Barbour Fellowship for the period 1927 to 1929 has been awarded to Dr. J. S. Fraser, who has been investigating for several years problems connected with the pathology of the ear. During the year under review twenty-one research workers have been actively engaged. Of these, seven were Fellows and two were Members of the Royal College of Physicians, while three were Fellows of the Royal College of Surgeons. The report outlines the scope of the work which was undertaken, the problems dealt with being not only pathological and bacteriological, but also physiological, chemical, and statistical. In 1929, 14,768 reports on experiments were prepared, 3,358 involving histological examination, 9,094 bacteriological work, and 2,346 chemical experiments. As in former years, the excess of expenditure over ordinary income was met by the Carnegie Trustees.

Australia.

[From our Correspondent in Victoria.]

The University of Melbourne.

The council of the Victorian Branch of the British Medical Association has collected a fund to commemorate the original researches in anaesthesia carried out by the late Dr. E. H. Embley. A memorial tablet has been unveiled in the Wilson Hall at the University of Melbourne, and a tablet will be placed in the Medical Society Hall. It is also proposed to establish a triennial E. H. Embley memorial lecture on the recent researches, principles, and practices in anaesthesia. With the consent of the Chancellor and the council of the University, some of the friends and old students of the late Sir Baldwin Spencer have decided to place a bronze medallion in the library of the Zoology School. Sir Baldwin Spencer was for many years professor of biology, and rendered valuable services to the University; he also conducted extensive researches among the Australian aborigines, the results of which have been embodied in book form. Professor Spencer met his death while he was engaged in studying the aboriginal inhabitants of Patagonia. His death is a great loss, not only to his many friends and old students, but also to the University and the community at large. By arrangement with the Melbourne permanent committee for post-graduate work Professor P. MacCallum has delivered a series of ten lectures on recent advances in applied pathology. The lectures were well attended and were much appreciated. Under the auspices of the same committee Professor Evarts Graham, professor of surgery at the Washington University School of Medicine, delivered a series of six lectures between July 17th and 25th. The subjects of the lectures were: pulmonary suppuration, physiology and pathology of the

gall-bladder, surgical treatment of pulmonary tuberculosis, cholecystography, the clinical significance of tests of hepatic excretion, and the significance of changed intrapleural pressures in the problems of empyema and other thoracic diseases.

The Armit Fund.

As foreshadowed previously in the *Journal*, a fund has been established in recognition of the valuable services rendered by the late Dr. Armit to the medical profession in Australia. Dr. Armit, whose sudden death occurred on March 12th, came to Australia in 1914, and became editor of the *Medical Journal of Australia*, a position he ably filled until the time of his death. He worked exceedingly hard, not only in the interests of that periodical, but also for the profession as a whole, and his valuable advice was always freely available for those who sought it.

Diabetic Control in Victoria.

A scheme for controlling diabetic mortality in Victoria has been submitted by the trustees of the Thomas Baker, Alice Baker, and Eleanor Shaw Medical Research Institute to the State health authorities and the council of the Victorian Branch of the British Medical Association. The scheme, slightly modified, has been approved by the council, and the chairman of the Public Health Commission has been notified to this effect.

Correspondence.

PERFORATING DUODENAL AND GASTRIC ULCERS.

SIR,—I have read with interest Mr. J. H. Watson's paper in the *Journal* of August 2nd (p. 169), and I should like to comment on my experience of this condition, which I regard as the most fatal common surgical emergency. During the past twenty months I have operated on, or been closely associated with, thirty perforations. All the patients except one were men, the exception was a woman aged 53, with a high gastric ulcer, who recovered. Thus this disease is not almost entirely limited to males.

The men fell into three classes.

1. *The Driver Class.*—These patients were bus, tramcar, engine, and lorry drivers, or conductors whose arduous occupations call for long hours of application and do not allow adequate opportunities for suitable meals with most important, an adequate relaxation period afterwards. They frequently eat their meal (sandwich type) while actually working. There were thirteen of these in my series, and ten recovered.

2. *The Casual Class.*—This includes labourers, unemployed persons, barmen, waiters etc., men whose lives consist of times of plenty with dietetic excesses and indiscretions alternating with times of poverty and exposure. There were eight in this group and five recovered.

3. *The Veteran Dyspeptic.*—These were all over 50, and included men in responsible positions—foremen, clerks managers, and retired business men, the eldest being 70. I had eight of this class and three recovered.

The following table emphasizes Mr. Watson's point as regards the season, the winter six months easily predominating.

Season	Recovered	Died	Total
Winter six months	15	10	25
Summer six months	5	1	6

I divide the ulcers into two groups: the pyloro-duodenal (including ulcers within one inch of the pylorus, on either side, and duodenal) and the gastric. The analysis is striking with regard to the mortality of gastric ulcers.

Type	Recovered	Died	Total
Gastric	2 (28%)	6 (75%)	8 (37%)
Pyloro-duodenal	17 (77%)	5 (23%)	22 (63%)
Total	19 (63%)	11 (35%)	30 (100%)

A survey of my series evokes the following comments. Pyloro-duodenal ulcers perforate more frequently than gastric, but the latter carry a much heavier mortality. The common age-period is 30–60; all the patients save one had been subject, "on and off, to indigestion for years" (frequently the patient's own expression), so that primary acute perforating ulcer is not a usual occurrence. The average time between perforation and operation was five and a half hours in the cases which recovered and eleven and a half hours in the fatal ones.

The causes of death were as follows: (1) Shock and *toxæmia in four cases, the patients were living caricatures,*" and died in six, thirteen and a quarter, forty-four and forty-eight hours. (2) Left intraperitoneal posterior subphrenic abscesses occurred in two cases, seven weeks after operation, and were only found with difficulty at the necropsy. (3) Torrential hæmorrhages from erosions of the coronary and gastro-duodenal arteries respectively in two cases. The ulcers were huge, the arteries presenting like white gaping papillæ in the ulcer floor; the sites of perforation were eccentric, near the edge, soundly healed and removed from the artery. Mr. Watson's technique might have saved one of these patients, but the gastric ulcer was high and excision would have been an extensive proceeding. (4) Paralytic ileus, general peritonitis with broncho-pneumonia, and gross phthisis (two months later) were responsible for the other three deaths. Post-mortem examinations were performed on most of these patients, and I was struck by the size of the ulcers; they were much larger than I had appreciated at the operation, the perforations were never central, and in all cases save one, where there was a slight leak, they were soundly closed.

Mr. Watson's symptomatology corresponds with my experience, but I would emphasize the fact that the pain is of the severe type, which immobilizes its victims, usually on their backs. This is a differentiating point from disease of the gall-bladder, appendix, and the high intestinal colic of sudden onset when the pulse is slow and the temperature normal but the pain causes patients to twist and turn about. I have only seen one patient with a perforation sitting up.

I aim at having these patients in bed and the operation performed within three-quarters of an hour of their admission to hospital. I split the right rectus, widely and carefully oversew the perforation, applying the usual Judd's omental patch. I only drain when there is gross food-soiling or over twelve hours' duration of perforation. The average operation time is ten minutes. I have given up more extensive procedures since my patients have been such sick men.

Mr. Watson's statement that the mortality should not exceed 5 per cent. is surely a counsel of perfection which hardly allows for extraneous complications such as phthisis and gross heart lesions, irrespective of those directly associated with the ulcer—peritonitis, hæmorrhage, and subphrenic abscesses. The standard of medical treatment of dyspepsia is now much higher, so that only patients with the most resistant and inveterate ulcerations, and in a correspondingly poor general condition, will perforate. I anticipate fewer perforations now but a poorer operation subject.

All my patients were given the intensive alkaline treatment shortly after operation: saline administrations, with glucose by the rectum and subcutaneous and intravenous routes, and blood transfusions, were used liberally; no stone of treatment and nursing being left unturned. The abdominal wounds, with one exception (a small stitch abscess), healed well by first intention; this shows that the peritoneal exudate is at the most only mildly infected.

The only man with a gastric perforation who reached aged 65 and 66 also recovered.

The only man with a gastric perforation who reached was the oldest in the series, a well-preserved man aged 70. Perforation and recovery at this age must surely be unusual and is worthy of a special note. Two other patients, aged 65 and 66, also recovered.

I am much indebted to Messrs. L. Barrington-Ward, T. Twining-ton Higgins, F. Sandy, J. Hunter, and W. B. Gabriel for permission to use the data of their cases for the larger part of this series.

—I am, etc.,

HAROLD DODD, Ch.M.,
F.R.C.S. Eng.

London, W.1, Aug. 4th.

This letter is written without the slightest intention of criticising the reviewer, to whom I am greatly indebted for his many complimentary remarks, but rather in the hope that it may to some extent clarify some of the points regarding local anæsthesia which are as yet not completely understood by any of us.—I am, etc.,

Muirkirk, U.S.A. July 25th ROBERT EMMETT FARR, M.D.

BLOOD CULTURE IN UNDULANT FEVER

SIR,—I read with great interest Dr. G. S. Wilson's letter in the *Journal* of May 17th (p. 926) in which he remarks: "It may be pointed out that CO_2 is absolutely essential for the growth of the bovine *abortus* type, and that a reduced oxygen pressure, as was used, for example, by Dr. Buxton, is not sufficient to ensure growth." This has not been our experience in Southern Rhodesia, where infectious abortion in cattle has been carefully studied by the Veterinary Research Department since 1915. Even when the serum medium advocated by McFadyean and Stockman in their classical report was used, cultures were obtained without regard to the CO_2 or oxygen content, and, since the methods of haemoculture and Stafseth have been employed, primary cultures have been even more readily obtained without these refinements.

In 1921 it was pointed out by the writer that certain cases presenting symptoms resembling those of undulant fever were occurring in this country in human subjects, who, so far as was known, could not have obtained infection from goats, but had resided on farms where cattle were, or had been, infected with infectious abortion; he suggested that these cases were suffering from an infection caused by the *B. abortus* of cattle. Since then some two hundred such cases have been reported, and it is now generally recognized that infection does take place in the manner suggested. Recently Dr. G. R. Ross, Rhodesian Research Fellow, London School of Hygiene and Tropical Medicine, investigated some of these cases, and demonstrated to the writer the ease with which he obtained primary haemocultures, without consideration of the oxygen or CO_2 content.

The discrepancy between Dr. Wilson's experience and our own is of considerable interest, and suggests that we may be dealing with a strain of *Brucella abortus* peculiar to this country, or, at any rate, different from the one obtaining in Great Britain. In order that this may be investigated I am sending cultures of four strains of the local organism to the London School of Hygiene and Tropical Medicine, and I shall be pleased to forward similar cultures to any readers interested in the subject.—I am, etc.,

LL. E. W. BEVAN,
July 7th Director of Veterinary Research, S. Rhodesia.

ANTIMALARIA MEASURES.

SIR,—In the *Journal* of July 5th (p. 40) Sir Malcolm Watson charges me with misrepresenting him in respect of his remarks at a meeting of the Royal Society of Tropical Medicine and Hygiene in October, 1924. He did, indeed, subscribe to the view that the future lay "in patient and searching investigation and in careful and continued experiment," but unfortunately he qualified his agreement by adding, "but the war stopped all chance of investigation and experiment." Since the war ended in November, 1918, and this remark was made in October, 1924, it is not obvious, if he considered further research was necessary, why he should regard the war as having put a stop to further investigation. In India, at any rate, research work on malaria was resumed immediately after the conclusion of the war.

Certain other considerations convince me that I did not misrepresent Sir Malcolm Watson's views when I stated that he considered the time was gone when investigation could serve any useful purpose in malaria control. In the first place, a few months before the meeting of the Royal Society of Tropical Medicine and Hygiene in October, 1924, he visited my laboratory in Lahore, when I have a vivid recollection that he not only spoke slightingly of the value of laboratory studies in malaria, but displayed little interest in a specially arranged exposition of the technique employed in the study of the epidemiology of malaria.

Secondly, if Sir Malcolm Watson held in 1924, as there is every reason to believe he did, that we already possess, in the shape of antimosquito measures, an effective means of controlling malaria in almost all circumstances then he would necessarily consider that time devoted to basic research would be much better employed in the practical work of eradicating mosquitos.

If, however, I have misunderstood and in consequence misrepresented him, I must express my regret but it is he now states, he is and always has been a strong advocate of further research, then it can surely only be because he has all along recognized that antimosquito measures do not constitute the first and last word in malaria control and that it is necessary, therefore if the immensely big and difficult problem presented by rural malaria in the Tropics is to be solved, "to search out and study the secrets of Nature by way of experiment." To which of these two views Sir Malcolm Watson now subscribes is not very clear, but one thing is certain, he cannot have it both ways.—I am, etc.,

C. A. GILL,
Simla, July 25th Lieutenant-Colonel, I.M.S.

DIFFRACTION METHODS IN DIAGNOSIS OF PERNICIOUS ANAEMIA.

SIR,—In the *Journal* of July 19th (p. 96) Dr. Malloy makes a praiseworthy effort to simplify for the clinician the detection of enlarged red corpuscles, and hence the early diagnosis of pernicious anaemia. He does this by looking at a candle through normal and suspected blood films, separating the resultant haloes by voluntarily squinting or by a prism. His article might, however, be misleading unless comments are made upon a few of his points.

1. Normal red cells vary so much in different people (from 4·5 to 5 degrees on the halometer) that by Dr. Malloy's method a small normal might be diagnosed as pernicious anaemia.

2. He observes his patient's progress by storing his previous blood films and comparing the latest blood film with them. This gives a fallacious impression of cure, because—even after fixation by methyl alcohol—the halo usually contracts: thus, for example 4·78 degrees becomes 4·55 in a month. Here again measurements are essential.

3. Dr. Malloy states that with Eve's halometer different observers may obtain different readings with the same slide, they will do so unless they examine the same area of the slide (ensured by an ink circle) for readings vary in different parts of a film. The only safe rule is to record the largest halo found. The first six readings by a schoolboy, aged 15, unused to the halometer, varied only by 0·04 degree.

4. He writes, 'pre-pernicious anaemia by its very definition is not accompanied by anaemia." My definition of it was "pernicious anaemia before it had reached its pernicious stage" (*Journal*, July 13th 1929, p. 48).

5. Rough qualitative methods are not enough for the responsible clinician who has to diagnose, exclude, or record progress in pernicious anaemia. He needs a handy instrument which will quickly measure red cell diameters so that they can be recorded for the use of himself and others. The halometer does this reliably if the film is thin.

6. Dr. Stanley Davidson (August 2nd, p. 193) writes: "I warn the practitioner against assuming that diffractive methods are a safe short cut to diagnosis, and that any method can dispense with a complete blood examination." But the problem for the general clinician—at least nineteen times out of twenty—is not to diagnose pernicious anaemia but to exclude it in suspicious cases. I have found the halometer reliable in this respect also. If its verdict is positive by all means confirm the diagnosis of pernicious anaemia by all the elaborate and expensive tests available, but this cannot be done in every suspicious case.

The main point is that the patient should not be allowed to miss the great benefit of liver diet when the bone-marrow demands it, as revealed by the occurrence of megalocytosis. I have had cases showing this pleasing benefit

although they may not have been pernicious anaemias in the strict sense. I have come to regard a small blood halo as an S.O.S. signal for liver, the condition being remediable unless treatment is too long delayed.

Finally, it is increasingly recognized that a pathological report on an anaemia (primary, at any rate) is not complete without a measurement of the average red cell diameter.—I am, etc.,

Hull, Aug. 6th. F. C. EVE, M.D., F.R.C.P.

THE NERVOUS ELEMENT IN RHEUMATISM.

SIR,—Viewing the prominence given of late to the question of rheumatic disease, it surprises me that no mention has been made of the obvious importance of the nervous element in these complaints. In the course of ten years' interest in the causation and treatment of rheumatism, I have had an opportunity of observing patients and methods in many countries. In no instance can I recollect seeing a patient suffering from any form of subacute or chronic rheumatism who did not also exhibit a more or less pronounced degree of nervous debility. Yet treatment is almost invariably directed to the physical side rather than to the nervous. Of course, the accompanying neurasthenia may often be explained by the secondary effect of toxic absorption or pain, but we have all seen cases in which neither of these factors has been of sufficient intensity to cause nervous discharge. A careful questioning of these patients will usually reveal some deep-seated anxiety or worry, and clinical examination will show diminished metabolism. This, as is well known, is an invariable result of anxiety. If there should happen to be a history of a former joint or muscular strain or injury, symptoms will primarily appear in that locality.

I cannot therefore subscribe completely to a belief in the toxic origin of chronic rheumatism, and, least of all, of such affections as sciatica and so-called neuritis. Naturally, a partly exhausted nervous and physical system may provide a happy hunting ground for any wandering bacillus, and so cause a complication, such as happens in rheumatoid arthritis, but this seems to be very often secondary. I feel more inclined to regard many cases as being examples of literal neurasthenia—quantitative deviation of nerve energy—realizing that a divided psyche can produce a local or general tissue dysfunction. Brodie, in the early nineteenth century, called attention to this aspect, and Timbrell Fisher emphasizes the importance of the mind, especially in cases where a functional element has been imposed upon a definite organic joint disease. I would like to stress the fact, which Fisher also mentions, that the functional or nervous element is very often primary, and eventuates in an actively diseased tissue. This is becoming increasingly common, due possibly to the fact that we are more highly sensitive beings to-day than ever before, and that we live in an age of marked nervous tension.

A classification of rheumatic affections points to three origins—physical, nervous, and toxic. The first appears to be more common in rural communities, the second in urban, and the third may be found in either. As to treatment, which, after all, is the most urgent problem, I am largely in agreement with Fortescue Fox—heat, moisture, and passive movement. I would include thorough twice-daily bowel evacuation, and a fruit and vegetable diet, or a well-balanced vitalized food intake. The employment, in suitable cases (which are many) of psychotherapy—hypnosis, psycho-analysis, or suggestion—proves advantageous. In intelligent patients, with purely or partly functional disabilities, psycho-analysis is the treatment par excellence. I believe that the time is not far distant when we shall be able to appreciate fully the nervous factor in all rheumatic diseases. On the physical side, I have found no method so effective as the pyretic technique of the late Dr. Wilde of Bath. The word technique is used advisedly, because the successful use of Wilde's thermal couch demands strict adherence to the principles formulated by its originator. I have found it superior to radiant heat, diathermy, and immersion and steam baths.

The profession has often been reproached for abandoning this immense and interesting field to the unqualified practitioner. Now that the urgency of adequate therapy is being realized, I feel sure that a broader understanding of the psychopathology of these wearisome affections will do much to lighten the burden of both medical attendant and patient.—I am, etc.,

Sydney, New South Wales, June 27th. E. HASLETT FRAZER.

INTRAVENOUS SCLEROSING SOLUTIONS.

SIR,—As Mr. Treves Barber suggests in the *Journal* of August 2nd (p. 195), it is most important that cases with untoward symptoms should be recorded. The first time I ever injected sodium morrhuate solution there resulted a reaction identical with the one recorded by Mr. Barber, the patient, a woman aged 23, having a severe urticarial attack which lasted a week. The ultimate result was splendid. On the other hand, I have used the quinine urethane solution for four years with excellent results, and with very few exceptions the reactions have been reasonably mild. The much discussed quinine reaction of headache, dizziness, and buzzing in the ears has not occurred in the last 800 injections, and there has been only one case of cramp in the leg, a condition that is not infrequent after sodium salicylate injections.

Contrary to Mr. Noel Scott's experience (*Journal*, July 12th, p. 58), I find that the proportion of injections that do not "take" is nearer 5 per cent. than 20 per cent. I make it a practice not only to warm the quinine solution, but to heat it up, and keep it hot by continuous immersion in boiling water, a result easily achieved by the use of a small spirit lamp. The temperature of the solution by this method will be about 200° F. by the time it reaches the vein, which is sufficient to produce a slight "scalding" of the intima, and thus to enhance the subsequent action of the quinine.—I am, etc.,

Manchester, Aug. 2nd. F. REYNOLDS.

THE DANGER OF BLOOD TRANSFUSION IN NEPHRITIS.

SIR,—A recent fatal experience during the course of a blood transfusion in a child 3 years old, with a very severe haemolytic anaemia and jaundice of unknown etiology, has recalled other similar catastrophies encountered usually in subjects with previously damaged kidneys. The danger of giving blood transfusions in such circumstances does not seem to be generally appreciated, and this letter is written in the hope of averting further calamities of this nature.

My attention was first directed to the possible dangers of giving a blood transfusion where the kidneys were previously damaged, despite the usual precautions with regard to grouping, by the unfortunate result which followed in a case of subacute nephritis seen about three years ago. The nephritis, which was due to a septic arthritis of the knee, was indicated chiefly by slight oedema of the legs, albuminuria, and the presence of casts and a few red blood cells in the urine. The daily volume of urine was satisfactory, and the blood urea about 60 mg. per 100 c.cm. A second operation on the knee had become imperative, but, since the patient was profoundly anaemic, it was decided to give a transfusion of blood first. The immediate effect was to reduce the output of urine to a few ounces daily, and to cause marked haematuria. Fortunately the man recovered. Since then I have met with, or heard of, six other cases, including the one published by Dr. L. J. Witts (*Lancet*, 1929, i, 1297); three of them were fatal, and four of the patients were known to have had a previous renal lesion.

In this connexion it should be remembered that severe jaundice from any cause is apt to be accompanied by temporary renal damage. The chief danger in these cases seems to be the production of anuria, though the manner in which this is brought about is not very clear. The most careful blood grouping does not prevent a certain amount of haemolysis, the products of which are known to be renal poisons. It is possible that a normal kidney can deal with these poisonous products where a previously damaged

symptoms, which may occur actually during the course of the transfusion, in some cases, suggests a general reaction of the nature of a protein shock the anuria resulting from an extrarenal factor, as in anaphylaxis

Whatever the explanation may be, it would seem desirable to urge that except in extreme emergencies a blood transfusion should not be given without a preliminary examination of the urine, and if there is any doubt, the renal function should be tested Dr Witts, in the article mentioned, suggests the prophylactic use of alkalis in such cases with the object of warding off anuria I have had no actual experience of prophylactic alkalinization in such circumstances, but from a considerable knowledge of their value in renal cases under rather similar conditions I consider this suggestion to be of great importance, and would recommend its trial —I am, etc ,

London, W 1, July 30th A ARNOLD OSMAN

LOCAL RESISTANCE TO INFECTION

SIR,—With reference to the letters on local resistance to infection in the *Journal* of June 14th and 21st I would suggest that this is surely a question of blood supply Wounds surgical or otherwise, in the perianal areas, including the urethra and vagina, and intra- and peri-oral wounds heal quickly for the same reason that wounds of the scalp whether inflicted with blunt or sharp weapons, heal very rapidly in the most unpromising circumstances Ordinarily, given a chance by the apposition of edges, and in the absence of general lowered resistance, *wounds which bleed freely heal quickly*—if I may be allowed to coin a surgical aphorism Here, in the second city of the British Empire I have had perhaps unequalled opportunities of observing this phenomenon, *so experto crede* —I am, etc ,

WILLIAM NOTAN, M D ,
June 17th Police Surgeon of Bombay

FIRST AID IN SERIOUS ACCIDENTS

SIR,—In the *Journal* of August 9th (p 229), Dr Henderson raises a very important question, and one requiring earnest consideration So far as the Order of St John is concerned, I have already, by advice and in competition work, drawn the attention of its Brigade to the absolute necessity of delaying transport until the patient is in a fit condition The question shall be raised again at the next meeting of the Brigade subcommittee for I entirely agree with Dr Henderson's remarks —I am, etc

C J ELLIS, Colonel
Torquay, Aug 5th Assistant Surgeon in Chief St John Ambulance Brigade

The Services.

TERRITORIAL DECORATION

THE Territorial Decoration has been conferred on Captain Kenneth B Dickson, R A M C , T F under the terms of the Royal Warrant, October 15th 1920

DEATHS IN THE SERVICES

Colonel Charles Alfred Atkins, late of the R A M C died in London on July 8th, aged 91 He was born on February 27th 1839 was educated at St George's and took the M R C S in 1861 and the L R C P Lond in 1862 Entering the A M D as assistant surgeon on September 30th 1863 he became surgeon colonel on August 1st, 1893, and retired on November 3rd, 1897 He served under Sir Garnet Wolseley in the Ashanti war of 1873-74, when he was present at the attack and destruction of Essaman Ampinee and Adubiasi, the actions of Abrakampra Amoafuh, and Ordahsu, and the final attack on and capture of Kumasi the capital; was mentioned in dispatches, and received the medal with a clasp Also in the second Afghan war of 1879-80, when he took part in the battle of Charasiah, where his horse was shot under him; in the operations round Kabul from December 11th to 23rd, including the defence of Deh Mazung Gorge, the assault and capture of Asmai Heights, and the defence of Sherpur cantonments, and the final repulse of the enemy; and in Sir Frederick (Lord) Roberts's march from Kabul to Kandahar, and the battle of Kandahar, was mentioned in dispatches in the *London Gazette* of May 4th and December 3rd 1880 and received the medal with three clasps and the bronze star As a regimental officer in his early service he served in the 7th Foot or Royal Fusiliers

Obituary.

ALFRED BERTRAM SOLTAU, C M G C B E, M D, F R C P F R C S

Physician to the South Devon and East Cornwall Hospital

THE death of Dr Alfred Soltau on July 26th at the age of 55, has removed an outstanding personality and terminated a career of devoted service

Alfred Bertram Soltau was born in 1876, and received his early education in Tasmania, returning to England for medical training at the London Hospital He graduated M B in 1900 with first-class honours in obstetrical medicine, and honours in medicine and forensic medicine, he obtained the diplomas M R C S L R C P in the same year He proceeded M D and obtained the diploma F R C S Eng in 1902 the M R C P in 1919, and the F R C P Lond in 1925 He early decided to practise in Plymouth, where his family had resided for several generations He was appointed physician to the Devon and Cornwall Ear and Throat Hospital, and later to the South Devon and East Cornwall Hospital, holding this latter post for a quarter of a century he was also consulting physician to the Liskeard, Tavistock, Kingsbridge, and Okehampton Cottage Hospitals, and a past-president of the Plymouth Medical Society He devoted much time and energy to the service of the British Medical Association he was one of the honorary secretaries of the Section of Medicine in 1907 when the Annual Meeting was held in Exeter a member of the South-Western Branch Council from 1909 to 1914 and vice-chairman of the Plymouth Division from 1912 to 1914 He was a member of the Plymouth Voluntary Hospitals Committee and vice-president of the Plymouth area of the St John Ambulance Association He was chairman of the committee of the South Devon Hospital Fete in 1921 when £5 000 was raised and presided over the United Plymouth Hospitals Fete in 1925 when £20 000 was received He found time to take part in local politics and was president of the Plymouth Conservative and Unionist Association as well as being a member of the Plymouth Borough Council from 1919 to 1925, and chairman of the Public Health Committee He associated himself actively also with the Boys' Brigade, and with numerous social and charitable institutions in Devonshire

For many years one of his special interests was military medicine He received a commission in the Devon Volunteer Brigade Bearer Company in 1905 and was the first commanding officer of the 2nd Wessex Field Ambulance (T F) When the war broke out he went to France in 1914 in command of a field ambulance two years later he was promoted to the rank of colonel and appointed consulting physician to the First and Second Armies In 1918 he became consulting physician to the War Office and to the Ministry of Pensions for cases of gas poisoning He was mentioned in dispatches four times created C M G in 1916, and C B E in 1919 he received the Territorial Decoration in 1921 His foreign decorations included the Croix de Guerre (France) and he was Commendador D'Ordre d'Aviz (Portugal) From 1922 to 1927 he was A D M S of the 43rd (Wessex) Division, and in the latter year was appointed honorary colonel He was appointed honorary physician to the King in 1924 He was joint author of the section on gas warfare in the Official Medical History of the War, and also of the Ministry of Pensions notes on certain diseases of the war He was a contributor to the *British Medical Journal* and other medical publications

We are indebted to Professor T. R. ELLIOTT for the following tribute:

The example of Soltau's life will not be forgotten by those who saw his work and knew the difficulties that successively faced him, but never crushed his courage or his resolution. His driving motive was a desire to do work for the common weal, an instinct that with him was devoid of any ostentation or personal ambition. He chose work that needed doing, and devoted himself to it with an unselfishness that may well have been the source of the courage which enabled him to continue unflinching in the face of ill-health, unperturbed as to who gained the credit provided that the work was done. Such motives are the quiet inspiration of many a doctor; Soltau neither wrote nor talked much about them. His personality missed that touch of open sympathy and cheerful buoyancy which gives a ready influence over others, but his actions were constantly shaped by such aims, while his energy and ambition brought him to positions in which he was able to do work of high importance. The best of this was achieved in the war. Long before 1914 Soltau had taken his share in the real duties of Territorial training, and soon after the outbreak of war he was out at the front in France with his field ambulance, though his position as a consulting physician in Plymouth would ordinarily have entitled him to remain at home attached to a civil hospital. His work in charge of this unit allowed of no specialization in those early days, but his abilities gradually became known, and he was naturally chosen for promotion to the rank of consulting physician to the Second Army when these new army appointments were made under Sir Wilmot Herringham as general consultant to all the armies. Colonel Soltau at once proved his right conception of the duties of a consultant in aiding the military efficiency of the army. He did not concern himself greatly with giving advice in the diagnosis of difficult cases or in the care of distinguished patients, but he flung his energies into teaching, organization, and the study of such conditions as were then imperfectly understood but were causing large numbers of casualties. Wounds of the chest soon passed from the physician to the care of the surgeons, and Soltau then became one of the acknowledged authorities on gas warfare poisoning. Trench fever had been proved by others to be the outcome of verminous infestation and dirt. Soltau fastened upon this great cause of the wastage of man power and the numerous casualties from other minor skin infections; and his diligent analysis month by month of the huge loss from these simple medical ailments gave great impetus to the efforts of the army authorities for checking wastage by keeping the men's bodies clean. Colonel Soltau himself contracted trench fever in the relapsing form, and this, together with his long and strenuous service abroad, exhausted him so much that in September, 1918, he had to be sent home to lighter duties, mainly in connexion with the control of casualties from gas poisoning. He left behind him a noble reputation for his knowledge of fighting conditions, his modern comprehension of disease, and his energy and judgement in acquiring and imparting fresh information gave his work an unsurpassed value.

In the Official History of the medical services in the war a considerable part of the section dealing with gas warfare was written by Colonel Soltau, and his wide knowledge of service conditions was made available to readers of the *British Medical Journal* in his reviews of various volumes concerned with different aspects of the war. He then settled down to recover his consulting practice in Plymouth. Troubles beset him with recurring trench fever and then with a keratitis that repeatedly threatened almost complete loss of sight. But he thought little of himself, and worked steadily for the advancement of medicine in Plymouth, the enlargement of the hospital, the provision of a really good pathological service, and the spread of knowledge by post-graduate teaching. Beyond it all lay the vision of a teaching medical school for the south-west of England. His last illness developed quickly, and early this summer he knew that it would be fatal. Even then he did not repine, and the last time that he talked with me he dwelt on the satisfaction that he had found in the opportunities for unstinted service that the war gave; he upheld the life of the consultant outside London because in it a man could so easily add to his professional tasks the pleasure of taking a useful part in civic work.

Dr. ERIC WORDLEY writes:

Recalling only his many-sided Plymouth occupations, it can be seen what a full life Dr. Soltau led; yet, numerous as they were, they only formed part of his activities. His consulting practice, extending throughout Cornwall and a large part of Devon, would have overworked any ordinary man, but in all that he did his interests were centred on his love for his profession and hospital, and I think he gladly undertook many of these further responsibilities because he felt he could at some time contribute something of service to these two ideals. In committee and in debate he was an outstanding personality; he was the acknowledged leader of his profession, who always pierced to the heart of things and could make an assembly visualize the larger issue. He worked unceasingly to make the South Devon Hospital a general hospital in the true sense of the word; nothing to be attempted on its behalf was too much trouble for him. An inspiring and enthusiastic teacher, he was the prime mover in starting and keeping going post-graduate classes during the winter months in Plymouth, and he spared no trouble or exertion to make these a success. His advice was constantly sought by his colleagues in all manner of affairs, and he went to endless trouble on their behalf until he could work no longer. Since the summer of last year he was constantly suffering from very severe attacks of pain, almost of an anginal nature; he slept badly, and was growing increasingly tired. For all this, his high and self-imposed standard of work for its own sake, and for the sake of his profession, never relaxed. Plymouth and the hospital he loved have lost a very great physician at the very height of his powers. He had a very lovable disposition, and inspired all with whom he came in contact to give their best: but in many ways he was intensely shy and diffident, and many people took him for a rather aloof and forbidding personality. Nothing really was further from the truth, and once one had the privilege of penetrating beneath this mask there was not a more open-handed or generous character; he had a delightful humour, but he hated arrogance and pretension in all its forms. No man rendered more ungrudging and unselfish devotion to his professional colleagues in their own time of trouble or sickness; however pressing other cares might be, however tired he himself might be, he was ready at a moment's notice to devote all his time and energies to any medical man, whether a colleague or no. He was a great example of that greatest of all virtues—unselfishness.

[The photograph reproduced is by Elliott and Fry.]

With the death, on July 29th, of Dr. JAMES ALLAN GRAY, at his residence in Stirling Road, Edinburgh, there has passed away one who was for many years a well-known practitioner in Leith. Born more than seventy-five years ago, he received his medical education in Edinburgh and Vienna, graduated M.B., C.M.Ed. in 1876, and proceeded M.D. in 1880, when his thesis was awarded a gold medal. In the same year he obtained the diploma M.R.C.P.Ed., and in 1881 proceeded to the Fellowship. After acting as resident physician to the late Dr. Muirhead in the Royal Infirmary of Edinburgh he settled in practice at Leith, and was for many years one of the physicians to the Leith Hospital. He was also a lecturer on clinical medicine to the women students of Edinburgh, at a time when they were excluded from the male classes and the clinical teaching in the Royal Infirmary of Edinburgh. Dr. Gray took great interest in the Volunteer movement, and was for many years a medical officer to the 5th V.B. Royal Scots, retiring with the rank of surgeon colonel in 1906, having received, in 1902, the Volunteer Decoration for long service. He acted for many years as medical officer of health for the burgh of Leith before it was united with the city of Edinburgh. Amid the many duties of hospital and private practice Dr. Gray found time to contribute to current medical literature. A paper entitled "Remarks on the use of hyoscine" was published in the *British Medical Journal* in 1892. Dr. Gray was a member of the British

Medical Association; he conducted a large practice until a year before his death, and was greatly beloved and respected by a wide circle of patients and professional friends. Two years ago, on the completion of fifty years' practice in Leith, he was the recipient of a testimonial from his colleagues. The interment took place in Rosebank Cemetery on July 31st.

DR. HUGH BOYD CUNNINGHAM, who died recently, was one of the leading ophthalmic surgeons in the North of England. He received his medical education in Newcastle-on-Tyne, London, and Vienna, and graduated M.B., B.S.Durh. in 1905. He was senior surgeon to the Durham County and Sunderland Eye Infirmary, consulting ophthalmologist to the Sunderland Royal Infirmary and Children's Hospital, oculist to the Sunderland Education Authority, and medical referee to the counties of Northumberland and Durham. Widely known throughout the whole of the county of Durham, Dr. Cunningham won the affection and respect of his many patients. He took particular interest in the problems relating to miners' nystagmus. He was a member of the British Medical Association, and was secretary of the Sunderland Division from 1922 to 1923; he was also a prominent Freemason. One of the chief interests in his life was the Durham County and Sunderland Eye Infirmary, where his skill and organizing ability were very highly appreciated.

THE LATE SIR FRANCIS CHAMPNEYS, BT.

DR. F. J. ALLEN (Cambridge) writes: In the obituary notice (August 9th, p. 231) mention is made of some of the musical accomplishments of Sir Francis Champneys, including the composition of anthems. But there are other compositions of his with which some readers may be more familiar, though unconscious of their authorship. As a young man, and under the name of "Frank Champneys," he contributed five tunes to *Hymns Ancient and Modern*, of which three—namely, Assisi (No. 119), Sales (No. 212), and Xavier (No. 421)—are the cognomens of three saints in the Calendar who bore his own name "Francis."

Medical News.

THE Royal College of Physicians of London will be closed for the summer vacation from Monday, August 18th, to Saturday, September 20th, both dates inclusive.

PROFESSOR G. GREY TURNER, honorary surgeon to the Royal Infirmary, Newcastle-on-Tyne, has been invited to deliver the John B. Murphy Oration before the Clinical Congress of the American College of Surgeons in Philadelphia on October 13th.

AT the International Conference of Bee-keepers, which will be held in London from September 8th to 12th, Dr. Kretschy of Austria will give a lecture entitled "Our bee as doctor," and Dr. Maximillian Grünsfeld of Vienna will speak on bee poison at the bedside. Further information about this conference may be obtained from its honorary secretary, Mr. F. Essex Moorcroft, Apis Club, 19, Devereux Court, Strand, W.C.2.

THE Fellowship of Medicine announces that there are two weeks remaining of the special course in genito-urinary diseases at the All Saints' Hospital, comprising clinical cystoscopic demonstrations on men and women. From September 1st to 13th there will be an all-day course in diseases of children at the Queen's Hospital; instruction will consist of the showing of a variety of cases rather than set lectures or demonstrations. The Westminster Hospital will hold the yearly revision course from September 15th to 27th; all departments of the hospital will be utilized for instruction in the various branches of medicine and surgery. The subjects of courses arranged for October are: diseases of the throat, nose, and ear; children; gynaecology, tropical medicine; orthopaedics; a general revision course; and evening courses for the M.R.C.P. and the Final F.R.C.S. Full particulars of the winter programme, a list of the special courses in 1931, and also information about the general course provided by the associated hospitals, may be obtained from the secretary of the Fellowship, 1, Wimpole Street, W.1.

THE Royal Microscopical Society, after having been housed in Hanover Square, London, for some forty years, has removed to new apartments in the British Medical Association House, Tavistock Square, W.C.1, its library and slide collections will be more adequately housed here, with its lecture halls, meeting rooms, and offices; a portion of its unique collection of historical instruments will also be on permanent exhibition. The ordinary meetings will be held as hitherto on the third Wednesday in each month from October to May inclusive, and henceforth in the Hastings Hall; by the almost unanimous vote of the Fellows these meetings will begin at 5.30 p.m. instead of at 8 p.m. as formerly. Sectional meetings will be held in the Pillar Hall.

THE KING has approved of the reappointment of Dr. Noel Leicester Clarke to be a nominated unofficial member of the Legislative Council of the Straits Settlements.

THE tenth Congress of the German Pharmacological Society will be held at Königsberg from September 4th to 7th, under the presidency of Dr. J. Schüler of Cologne. The principal subjects for discussion will be the problems of inflammation; the pharmacological problems of febrile diseases; allergy; and the problems of the reticulo-endothelium.

THE twelfth Congress of the French Society of Orthopaedics will be held on October 10th in the Paris Faculty of Medicine, when the subjects for discussion will be coxa vara in adolescents, and obstetrical paralyses in the upper limb. Members of the society—whether French or from other countries—who intend to take part are asked to communicate, before September 15th, with the secretary, Dr. E. Sorrel, 179, Boulevard Saint-Germain, Paris.

THE annual medical tour to spas and other health resorts in Italy, organized for British doctors by the Italian State Tourist Department, will take place from September 10th to 26th. As usual, it will be accompanied by an English-speaking Italian doctor. The journey in Italy will be made by special train; there will be no night travel. Accommodation is provided at first-class hotels, and a programme of receptions, entertainments, and sight-seeing has been arranged at each of the places to be visited, which include Merano, Carezza (Karersee), and other Dolomite resorts, Riva and Gardone on Lake Garda, Montecatini, and Viareggio. Full particulars may be obtained from the Italian Travel Bureau, 16, Waterloo Place, S.W.1.

AN account of a tour of some mental hospitals and clinics of the Department of the Seine, by Dr. A. E. Evans, which was published in the January issue of the *Journal of Mental Science*, has now been reprinted in pamphlet form, and may be obtained from Adlard and Son, Ltd., 21, Hart Street, W.C.1, price 1s. net.

A FURTHER series of brochures—Nos. 206 to 212—has been issued by the International Labour Office in continuance of its series entitled "Occupation and Health." The subjects are: flour mills; garages, industrial health (propaganda), house porters; industrial lighting, industrial physiology and jute. They may be obtained from the London office of this organization, 12, Victoria Street, S.W.1.

ON the passing of the Mental Treatment Act the Board of Control, with the approval of the Minister of Health, has appointed Mr. P. Barter of the Ministry of Health to be joint secretary of the Board. Mr. Barter was secretary to the Committee on Asylum Administration, 1921-22; the Royal Commission on Lunacy and Mental Disorder, 1924-26; and the Royal Commission on Local Government, 1926-29.

THE council of the Paris faculty of medicine recently elected Professor Balthazard, who occupies the chair of legal medicine, dean of the faculty by 34 votes, to 33 gained by Professor Roussy.

THE centenary of the birth of the celebrated French physiologist, Etienne Jules Marey, who died in 1905, was recently celebrated at the Academie de Medecine, when Professor Charles Richet gave an address on his work.

THE two Osiris prizes, each of the value of 100,000 francs, offered by the Institut de France for the most remarkable work in science, literature, and art, have been awarded to Paul Bourget of the Académie Française, and Emile Gley, professor of physiology at the Collège de France.

THE Grand Prix de l'Académie Française, of the value of 15,000 francs, has been awarded to Dr. Georges Duhamel for his collected works.

A NEW dermatological clinic has recently been opened at Leyden under the direction of Dr. H. W. Siemens.

IN Berlin, during 1929, 6,925 deaths, or 13 per cent. of the total mortality, were due to malignant growths. Cardiac disease, principally in advanced age, caused 6,776 deaths, and pulmonary tuberculosis 4,071 deaths, chiefly between the ages of 20 and 30. Most of the deaths from cerebral haemorrhage (5,560) and vascular disease (5,065) occurred in persons over 50.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. *Correspondents who wish* notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the *Financial Secretary and* Business Manager.

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL, Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

DERMATITIS FOLLOWING FURUNCULOSIS.

DR. C. MURRAY HALSALL (Ilkley) writes: I should be grateful if someone would suggest a form of treatment which has been tried with success for dermatitis following furunculosis. My patient, a man aged 50, has had furunculosis for two years, and recurrent attacks of dermatitis for one year, with hardly any intervals.

TREATMENT OF DYSMENORRHOEA.

DR. E. R. B. MURRAY (Clitheroe, Lancashire) writes: Could any reader give me suggestions for the treatment of dysmenorrhoea in a young woman aged 22? She has had a dilatation and curettage, and subsequently the round ligaments were shortened. No organic disease was found. She still has very severe pain, especially during the first day. An exhaustive trial of medical measures has been made.

CLEANSING OF THE CHALICE.

"S. M." writes: I think it is worth while recording my experience in this connexion. I was at one time a strict and regular communicant, but having on one occasion to partake of the cup after a consumptive and a man with septic teeth had already drunk from it, I suggested to the officiating clergyman, who was and is a friend of mine, that at the least he might wipe the rim of the chalice with a "fair linen cloth." He told me to be of good cheer and to have no fear, because the cup was automatically sterilized when he sanctified it, and remained so in spite of septic teeth and mouth. After that I remained at home, and have never been to communion since. It is really time that some clergy learned that there is such a thing as hygiene. I am quite sure that the majority of them are just as particular as the rest of us about not drinking after other people from the same cup in their own homes.

DR. EVA MCCALL (London, W.1) writes: The notes in recent issues of the *Journal* as regards cleansing of the chalice recalls to my mind a statement made by a dermatologist, now dead, in the course of a post-graduate lecture. He said that he had ceased to partake of communion since the day when he found that his neighbour at the altar rail was a patient whom he had been treating for syphilis.

COLOUR-BLINDNESS.

DR. H. E. ROAF (London, N.W.), replying to "A. B." (August 2nd, p. 200), writes: By the use of red glass some colour-blind individuals can discriminate colours. Colour-blindness is no handicap for medicine, but it is a bar for the navy, mercantile marine, and railways, or work which necessitates the recognition of coloured signals.

INCOME TAX.

Residence in United Kingdom.

"J. B. M." is living in India but is thinking of taking a house in the United Kingdom for the use of his wife and children. Will that render him liable to English income tax on (*a*) sums remitted from India to England, and (*b*) income from English investments? Also, if he purchases a house and it remains vacant, will that affect his liability?

*** The establishing of a residence in this country for the use of his family will bring our correspondent within the category of a British resident, and will render him liable to account for United Kingdom income tax on the amount of remittances out of his foreign income, less, of course, the usual personal and children's allowances. The income from British investments is liable to British tax in any case. One exception to that rule, however, is interest on the 5 per cent. war loan, the recipient of which is exempt if not "ordinarily resident" in the United Kingdom. Assuming that the residence is to be established here for a temporary purpose, we consider that our correspondent would not thereby forfeit his claim to exemption in respect of war loan interest. It will be seen that the crux of the matter is residence and not merely the possession of property in the United Kingdom. If, therefore, a house be owned here, but is in fact not furnished and available for immediate occupation by the owner, its possession would not render him liable for income tax, except in respect of any rents derived therefrom.

Emoluments of Appointment.

"A. C.'s" employment began as from September 23rd, 1927, at the rate of £250 per annum. The emoluments for the year to April 5th, 1929, amounted to £299 10s. What special relief is he entitled to in the early years of his employment?

*** The basis of assessment normally is the income of the previous year, but as this might work unfairly as regards the early years of an appointment it was provided, by Section 45 of the Finance Act, 1927, that the basis of assessment should be as follows: (*a*) From commencement to following April 5th—amount of emoluments for that period. (*b*) Following financial year—amount of emoluments for that year. (*c*) Next financial year—same amount as in (*b*) unless the emoluments for the actual year are less, when the taxpayer can claim reduction to the actual basis. Applying these rules, "A. C.'s" liability would be on £299 10s. for 1928-29, and on the same amount for 1929-30, unless that year's salary was less, in which case he can claim "relief" by reduction to that figure. For 1930-31 he is assessable on the amount receivable for 1929-30.

LETTERS, NOTES, ETC.

OPPORTUNITIES FOR TEACHING IN GENERAL PRACTICE.

MR. H. W. WEBBER, formerly surgeon to the South Devon and East Cornwall Hospital, writes from King's Tamerton: Could not some plan be considered whereby the wealth of clinical material in the surgeries of general practitioners might be utilized for instructing students? An illustration will explain my meaning. Recently I was assisting a practitioner with his "evening surgery," and he asked me to overhaul a new case. The patient, a man aged 65, formerly a drill sergeant, complained at first of symptoms referable to the nervous system, but on proceeding with his history he mentioned shortness of breath and pain in the left side of the chest. On examination the pupil reactions, mouth, oropharynx, and neck presented nothing abnormal. The chest was a typical example of emphysema—no liver dullness, no superficial cardiac dullness, and the breath sounds characteristic. The apex beat of the heart was not palpable, its sounds weak and muffled, and no bruit was audible. There was nothing abnormal in the abdomen. The legs were oedematous below the knees. The urine was high-coloured, of specific gravity 1025, and contained no albumin. Now here was an excellent case for demonstration to a student, illustrating common diseases such as he would meet and be called on to treat in practice—emphysema and cardiac failure. I saw other interesting cases, including a hydrocele of the tunica vaginalis, a condition commonly met with in practice, and not unknown in the clinical part of final examinations. All general practitioners must meet with such cases as the above. I suggest that students who cared to do so might attach themselves to a practitioner during their holidays from work at the hospital. In the daytime they could pass the hours according to their inclination, and in the evening attend a surgery. They might make themselves useful by dispensing and bookkeeping, and in return the practitioner would, when a suitable case presented itself, demonstrate the points of interest in diagnosis and treatment. Perhaps the Association might keep a register of practitioners willing to undertake this work, and by this means intending students could get into touch with them.

POSITIVE SPUTUM IN ACUTE MILIARY TUBERCULOSIS.

DR. W. E. ROPER SAUNDERS (Staffs) asks us to express his regret that in the note in the *Journal* of April 19th (p. 768) he omitted to mention that the case described therein was brought to his notice when district tuberculosis officer for the Durham County Council by Dr. J. Jennings of South Street, Durham.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 37, 38, 39, 40, 41, 44, 45, and 46 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 42 and 43.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 120.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

142. Post-vaccinal Encephalitis.

C. M. BELLI (*Rinascenza Medica*, July 1st, 1930, p. 305), in a review of post-vaccinal encephalitis, states that about 500 cases have occurred, mostly in England and Holland; there have been 50 in Germany, 12 in France, some in Switzerland, Greece, Austria, and the United States, but none in Italy and Spain. Most of the cases occurred in children vaccinated for the first time between the ages of 5 and 14 years; the disease spares babies vaccinated soon after birth, and is therefore absent in countries with compulsory vaccination. It is rarer in revaccinated persons. Heckman cured seven boys suffering from post-vaccinal encephalitis by inoculating serum obtained from parents who had been successfully vaccinated at the same time. Other evidence tending to associate this condition with vaccination is that vaccinia virus has been isolated from the brain of patients who have died of post-vaccinal encephalitis, and the similarity of the incubation periods. Epidemics of post-vaccinal and epidemic encephalitis do not coincide; moreover, post-vaccinal encephalitis has a quicker onset, shorter course, fewer sequels, and smaller mortality than the epidemic form, and its lesions predominate in the white matter. The motor paralyses are often confined to the vaccinated side. In England and Holland it has appeared without connexion with the type of lymph used. In Holland neurovaccine, prepared in Spain by direct inoculation into the rabbit's brain, was tried; there were 11 cases of post-vaccinal encephalitis in 40,000, while Spain recorded none in 2,000,000. The incidence is unaffected by virulence. Belli concludes, therefore, that it is unlikely that the vaccinia virus is the cause; there is no evidence of predisposition, and, in view of the rigorous control, it is improbable that impurity of the lymph plays a part. Kling, Lönberg, and Wassen found in brain sections oval or rounded corpuscles containing chromatin masses colouring deeply with Giemsa's stain; these they considered to be "latent" protozoa, activated by vaccination. The treatment includes the intravenous injection of sodium salicylate and the serum of a vaccinated patient. Belli urges that vaccination should be practised during the first year of life, except in illness or during outbreaks of epidemic encephalitis. Two short parallel scarifications should be made, not too close together. The lymph should be obtained from the calf or ass, and not from the rabbit.

143. Etiology and Prognosis of Auricular Fibrillation.

H. COOKSON (*Quart. Journ. Med.*, April, 1930, p. 309) describes certain obvious sequels of auricular fibrillation, such as the lowered ventricular efficiency following irregular and still more rapid contractions. Other less obvious factors coincide with the advent of arrhythmia. There are only three common etiological groups in which arrhythmia is persistent. Most frequently it is associated with rheumatic carditis. Age is a constant factor in the second group, while, in the third, exophthalmic goitre or some allied toxic thyroid condition is present. The second group, containing middle-aged or old patients, has been termed "arterio-sclerotic," but the associated sclerosis is not greater than that of the age period concerned. Conversely, in patients who have conspicuous sclerosis, normal rhythm is the rule; also, in coronary thrombosis, usually associated with atheroma, fibrillation is rare. Paroxysmal fibrillation occurred in only 7 per cent. of one group of patients, and histological evidence failed to incriminate the arteries. In ten cases of the so-called "arterio-sclerotic" type, only one patient showed considerable atheroma. Some of the other patients had definite atheroma of the peripheral arteries, and ischaemic renal changes. This series negatives the theory of coronary arterio-sclerosis as a cause of fibrillation. In ten other patients who had had normal rhythm the necropsy showed more extensive coronary atheroma than was found in patients who had had fibrillation during life. Cookson thinks that the term "arterio-sclerotic auricular fibrillation" must be rejected. Hyperplesis is too infrequent in these cases for it to be regarded as an important factor. The term "senile type" is unsatisfactory, since it exaggerates the average age incidence; numerically, this type is second only to the rheumatic type in causing persistent auricular fibrillation. The author suggests the term "non-rheumatic group" for this type, excluding, of course, the distinct and smaller group of toxic goitre cases. In a series of 361 cases of fibrillation, 69 per cent. had rheumatic carditis or a history of rheumatic fever; 22 per cent. were not rheumatic; 7 per cent. had associated exophthalmic goitre; and 2 per cent. had syphilitic aortitis. Contrary to the experience of other writers, Cookson found that among the non-rheumatic group a larger percentage developed heart failure at the onset of fibrillation. Auricular fibrillation is rare in the first decade of life and still rarer in the second, while the prognosis is very bad; the average length of life after onset of fibrillation in twenty-three patients under the age of 17 being ten months only. Among adults the average duration is 5.25 years. In mitral stenosis, embolism occurs as frequently in cases with a normal rhythm as in those with arrhythmia. When partial heart-block occurs apart from treatment the prognosis is better in patients who have arrhythmia, which does not appear to increase the gravity of a case in which complete block already exists. When the two disorders were associated Stokes-Adams attacks rarely occurred. The prognosis is adversely affected by bundle-branch block, but not by spontaneous premature ventricular contractions. The auricular oscillations of the electrocardiogram are usually smaller in the non-rheumatic than in the rheumatic type. There is little evidence of connexion between the duration of the fibrillation and the amplitude of these waves. Angina of effort, coexistent with fibrillation, occurred five times in 2,000 patients with arrhythmia. In coronary thrombosis the advent of fibrillation occasionally eases the pain: relief seems more likely if congestive failure occurs. Infective endocarditis and fibrillation are both common sequels of rheumatic carditis, but are associated very rarely. Sudden death is not infrequent in auricular fibrillation; the theories advanced to explain this were found inadequate in the series of cases studied.

144. Post-influenzal Angina Pectoris.

A. S. HYMAN (*Journ. Amer. Med. Assoc.*, April 12th, 1930, p. 1125) records nine cases of angina pectoris which occurred among 412 cases of acute influenza, and was first described by Sansom in 1892. Of the nine patients three died, one in the first attack, one in the second, and one in the sixth attack. Five had no previous cardio-vascular history, and one had a questionable history of high blood pressure a few years before. All the patients were middle-aged. Hyman found no relation between the severity of the original influenzal attack and the time of the onset of the first anginal seizure, or between the onset and the outcome. The electrocardiograph provides the only method for determining the extent and severity of the myocardial changes, which were marked in most cases. The author concludes that post-influenzal angina pectoris is a not uncommon sequel in convalescence from influenzal infections occurring in the middle-aged. If cardio-vascular changes are noted, the period of convalescence should be prolonged to allow the heart to recover fully. If angina pectoris is at all suggested by electrocardiographic examination expectant treatment should be started at once.

145. Scarlet Fever and Endocarditis.

H. ZISCHINSKY (*Jahrb. f. Kinderheilk.*, May, 1930, p. 337), who records several illustrative cases, states that scarlet fever plays no important part in the etiology of cardiac valvular defects. In a few very exceptional instances an endocarditis may be found at the necropsy in a case of scarlet fever. Such cases, however, represent a septico-pyaemic manifestation and are invariably fatal. In order to justify the diagnosis of scarlatinal endocarditis the following conditions must be fulfilled: either a recent endocarditis of the valves must be demonstrated, or the change in the clinical finding of endocarditis into a permanent valvular defect must be established by several subsequent examinations made for months or years.

146. Severe Cerebral Symptoms following Stovarsol Administration.

ALTHOUGH stovarsol has been recommended in recent years as a substitute for salvarsan in syphilis and other spirochaetal diseases, a case recorded by BERTA ASCHNER (*Wien. klin. Woch.*, May 8th, 1930, p. 581) shows the danger of excessive doses. A woman, aged 34, developed an attack of Vincent's angina. Eight tablets of spirocid, a stovarsol preparation, were administered daily for four days, succeeded by four tablets daily during the next four days. These doses are very large, for usually this quantity of stovarsol would be spread over two weeks, being administered every two or three days and followed by an interval; only exceptionally should a daily

dose of four tablets (0.25 gram) be given. On the ninth day an extensive arsenical dermatitis appeared, and two days later the patient suddenly developed severe mental confusion with a bilateral Babinski sign. The spleen was palpable. There were no paralyses or clonus, but the tendon reflexes were very brisk, and there was a bilateral pseudo-Babinski reaction. Kernig's sign was absent. The urine was then normal. Next day the patient was unconscious, with severe hyperaesthesia of the skin so that she screamed at the slightest touch, and could not urinate for several days, so venesection and sweating treatment were prescribed. Six days after the onset of these severe toxic symptoms the patient urinated spontaneously. Venesection was repeated and calcium was injected intramuscularly. During the night the patient recovered consciousness suddenly. Arsenic was then present in the blood and the urine, but complete recovery ensued.

147. Diphtheria of the Penis.

A. L. HOYNE and A. J. LEVY (*Journ. Amer. Med. Assoc.*, May 3rd, 1930, p. 1395) indicate the rarity of diphtheria of the penis by reporting a case, the only one which has occurred among 14,000 cases of faucial diphtheria treated at the Municipal Contagious Diseases Hospital, Chicago, since it was opened in 1917. Usually diphtheria of the penis is secondary to some other diphtherial lesion in the body, but some cases have been recorded in which the infection was primary in the genitals. The present instance, in which the patient was a boy aged 7, is the first on record occurring in a circumcised person; circumcision had been performed in infancy. The penile lesion was associated with severe faucial and nasal diphtheria. Recovery followed large doses of antitoxin.

Surgery.

148. A Plastic Operation for Facial Paralysis.

W. O. LODGE (*Brit. Journ. Surg.*, January, 1930, p. 422) describes an operation which is designed to ameliorate disfigurement and to prevent impending corneal ulceration in long-standing cases of lower-neuron facial paralysis, especially those due to mastoid disease, or accidentally inflicted during mastoid operations. Though suitable cases are rare, the results obtained in one case merit a more extended trial of the method. In this procedure, without leaving conspicuous scars, three new ligaments are grafted into the face, corresponding in position with the inferior portion of the orbicularis oculi, the levator palpebrae superioris alaeque nasi, and the zygomaticus major. These sustain the drooping lower eyelid and paralysed side of the mouth, and produce a more pleasing expression. The material employed is a continuous strip of fascia lata obtained from the thigh. General anaesthesia is induced, and the skin, conjunctiva, and buccal surface of the cheek are thoroughly disinfected with 2 per cent. mercurochrome solution. A probe is passed along the inferior lacrymal canaliculus to define its position; the angular vein and parotid duct must also be avoided in the subsequent operation. Two short incisions are made, exposing the temporal fascia and the internal palpebral ligament respectively. A third tiny incision is made at the junction of skin and mucous membrane at the angle of the mouth. The strip of fascia lata is threaded along a triangular course between the three facial incisions, among the atrophied muscles, with a packing needle, the internal palpebral ligament and orbicularis oris being encircled. The two free ends are drawn tight and woven into the fibres of the temporal fascia. The incisions are closed, and the tension is temporarily relieved with adhesive strapping. The result is not so good as is obtainable in cases of shorter duration by facio-hypoglossal anastomosis, but the method has one real advantage in producing an immediate effect.

149. Intravenous Urography.

A. L. WOLBARST and I. S. HIRSCH (*Med. Journ. and Record*, July 2nd, 1930, p. 1) claim that with the introduction of uroselectan an important advance has been made in urological diagnosis, and that pathological conditions, in which other measures cannot be employed, can be diagnosed with its aid. Uroselectan, which has an iodine content of 42 per cent., is non-toxic, very soluble in water, and neutral in reaction; under normal conditions it is excreted as such through the genito-urinary tract, practically to the extent of 90 to 100 per cent. within eight hours, which indicates that no chemical reaction takes place in the body. The iodine in the molecule exists in a very stable organically bound state; therefore the relatively large quantity of the calculated iodine element in uroselectan can be administered with impunity. Iodism has never been observed. The method is based on the excretion of the contrast substance by the kidneys. The more normal the kidneys, the greater their excretion and the more constant and complete is the outlining of the urinary tract. Since 85 to 90 per cent. or more of the iodine content can be recovered in the urine within six to eight hours in cases of normal kidney function, the drug affords a test of renal function in addition to its urographical rôle. In a large series of cases von Lichtenberg and Swick concluded that when no picture of the kidneys is obtained, either no kidney is present or the renal function has been largely destroyed. They sum up the indications for this method as follows: when cystoscopy and ureteral catheterization cannot be performed because of anatomical or other reasons; when because of obstruction in the ureter the contrast substance cannot be injected beyond the block; when direct pyelography cannot be undertaken without risk. The technique of intravenous urography, which is very simple, is described. The first radiogram is made twenty minutes after the injection, and a second examination is made twenty minutes later. The patient is then allowed to pass a little urine, to diminish the bladder shadow and to permit better visualization of the lower portions of the ureters. Three subsequent radiograms at intervals of twenty minutes are then taken. It is possible to draw reliable conclusions as to functional activity according to the time required to attain visualization, and by comparison of the two sides. The conclusions in regard to disturbed function are based on the time of visualization of the contrast substance and the degree of intensity of the shadow. The method may also be used in cases of enlarged prostate to ascertain the effect of stagnation on the upper urinary tract, and to demonstrate the dilatation of the renal pelvis and ureters.

150. S. LUBASH (*Amer. Journ. Surg.*, June, 1930, p. 1229) emphasizes three points in intravenous urography with uroselectan—namely, the importance of exercising compression over the bladder area with an ordinary Hickey rubber bag, increasing the dose of this drug to 60 grams, and postponing urination. It is claimed that by these means a denser radiogram is produced; the increased dosage has no untoward effect, and the external compression improves visualization. Pressure to just below the degree of discomfort is applied immediately after the last injection of uroselectan and until the first film is taken; it can then be slightly reduced, but is increased ten minutes before and during the exposure of the second film. The pressure is then completely relaxed, but is reapplied ten minutes before and during the third, fourth, and succeeding exposures. Swick, who last year introduced the non-toxic uroselectan for intravenous injection, advocates a 60-gram dose instead of the original one of 40 grams; the solution is prepared by dissolving the drug in warm twice-distilled water to a volume of 110 c.cm.; it is then filtered twice through ordinary filter paper, and sterilized in a water bath at 15 lb. pressure for half an hour. Urination is postponed until after the second exposure, but if this retention produces too great discomfort the passage of a small quantity sufficient for comfort may be allowed, or relief obtained by slightly reducing the pressure of the rubber bag.

151. Bronchiectasis.

P. N. CORYLLOS (*Archives of Surgery*, May, 1930, p. 767) distinguishes four different clinical varieties of bronchiectasis: (1) a bronchitic form in which the bronchial lesions are slight, the parenchyma of the lung is healthy, and the classical symptoms of bronchiectasis are absent; (2) early uncomplicated bronchiectasis in which bronchial lesions are still limited to the bronchi; (3) complicated bronchiectasis with more or less advanced pneumonitis or small multiple bronchiectatic abscesses; and (4) bronchiectatic abscesses. Bronchiectasis is a common pulmonary disease; it frequently follows measles, scarlet fever, and chronic inflammation of the paranasal sinuses in children. It has been stated that 25 to 50 per cent. of sanatorium patients have bronchiectasis, while 20 per cent. of all cases of chronic tuberculosis and 10 per cent. of cases of tumour of the bronchi and lungs, foreign bodies, or extrinsic compressions of the bronchi are complicated by bronchiectasis. Treatment depends on the form of the disease. In the bronchitic form, treatment of the paranasal sinuses, a hot dry climate, and postural and bronchoscopic drainage may check the disease. In early cases, particularly of unilateral bronchiectasis, therapeutic compression of the lung (pneumothorax, phrenicectomy, or thoracoplasty, associated with postural and bronchoscopic drainage of the bronchi and antispirochaetal treatment) have given satisfactory results. In the advanced form of bronchiectasis with pneumonitis and multiple bronchiectatic abscesses the only treatment is the surgical excision of the diseased portion of the lung by lobectomy, cautery pneumectomy, or exteriorization and ligaturing of the involved parenchyma of the lung. Since the disease is progressive, early treatment is of great importance. In order to

decrease the high mortality rate of 55 per cent. incidental to one-stage operations, a technique of multiple stage lobectomy is advised in which artificial pneumothorax, phrenicectomy, thoracoplasty, and lobectomy are performed in the order given. Two cases are recorded of advanced bronchiectasis; they were treated by graded operation with excellent results, and the complete recovery of the patients.

152. Incidence of Primary Carcinoma of the Lung.

FROM a statistical review of the literature P. D. ROSAHN (*Amer. Journ. Med. Sci.*, June, 1930, p. 803) concludes that primary pulmonary carcinoma is not so rare as was formerly believed, and that its incidence is steadily increasing. Of 3,034 adult necropsies performed at the Boston City Hospital from 1910 to 1928, 314, or 10.4 per cent., were cancer cases. Primary pulmonary carcinoma occurred in 23, or 0.7 per cent., of all adult necropsies, and 6.69 per cent. of all cancers. Combined statistics show that primary carcinoma of the lung discovered at post-mortem examinations from 1910 to 1919 comprised 0.44 per cent. of necropsies and 4.39 per cent. of all cancers. Since 1920 the figures have been 0.89 and 6.93 per cent. respectively. Opinions differ with regard to the question whether this increase, noted by practically all observers, is an absolute one, peculiar to the lung, or only relative to and coincidental with a general increase in systemic cancer. For reasons which are cited Rosahn inclines to the former view, and considers that, because of its increased frequency, clinicians should give this affection serious consideration in differential diagnosis in patients of the carcinomatous age presenting puzzling lung symptoms and signs. An early diagnosis will permit of accurate prognosis, and in selected cases, perhaps, surgical therapy.

153. Post-operative Intestinal Paralysis.

BARTHÉLEMY (*Bull. et Mem. Soc. Nat. de Chir.*, May 24th, 1930, p. 637) records four cases (one a personal case) of post-operative intestinal paralysis in which injections of hypertonic saline serum resulted in almost immediate relief. In the personal case, after a somewhat difficult retrocaecal appendicectomy, the usual symptoms of intestinal paralysis supervened—namely, drawn facies, weak pulse, abdominal ballooning, vomiting (which became bilious and finally faecal), and retention of both faeces and gas. A subcutaneous injection of peristaltine having produced no effect, an intravenous injection of 40 c.cm. of 20 per cent. saline serum was given on the third day after operation. This was followed in ten minutes by a small but uncontrollable vomiting, giving the impression of an intense gastric contraction which was not attributable to the trivial amount of the stomach's contents. Some hours later, and without other medication, the patient passed a large stool mixed with blood, and marked improvement was noted on the next day. A second injection of 40 c.cm. of the serum was given, and this was followed by a complete and rapid return to normal. Reference is made to the benefits of this treatment in cases of intestinal paralysis following acute gastric dilatation and colostomy. Barthélemy agrees with the suggestion of Gosset as to the probable action of injections of hypertonic saline serum on the intestinal musculature.

Therapeutics.

154. Idiosyncrasy to Alkaloids of the Cinchona Group.

W. T. DAWSON and F. A. GARBADE (*Journ. Amer. Med. Assoc.*, March 8th, 1930, p. 704), in a preliminary report, state that the accidental discovery by one of them of a personal idiosyncrasy to quinine led them to investigate his sensitiveness to both the other laevo-rotatory alkaloids of the group and their dextro-rotatory isomers. By means of Boerner's test (scarification of the skin through solutions of 1 to 10 per cent. of the alkaloids or their sulphates) sensitiveness to all the laevo-rotatory alkaloids was demonstrated, whereas a negative reaction was obtained with all the dextro-rotatory isomers; a positive reaction consists in the production, in 15 minutes, of an urticarial wheal. When a sulphate is used in acid solution the acid must be under 10 per cent., since otherwise a pseudo-positive reaction ensues. The laevo-rotatory substances are cinchonidine, hydroquinine, hydrocinchonidine, cupreine, hydrocupreine, ethylquitinine, and ethylhydrocupreine (optochin). The negative reactions in the isomers were checked by the oral ingestion of quinidine and cinchonine; ingestion of 0.5 grain of cinchonidine gave rise to mild cinchonism. Other alkaloids were not taken orally for fear of dangerous side-reactions. It was found in the case of two other persons that, in spite of a negative Boerner test, urticaria followed the ingestion of quinine. It is concluded that a positive test presages a stormy general reaction to one or more of the alkaloids, whereas an urticarial reaction may occur in spite of a negative test. The clinical importance of the test lies in the possibility of substituting a therapeutically active isomer where an idiosyncrasy is found to exist—for example, cinchonine for quinine in the treatment of malaria.

155. The Therapeutic Value of Magnesium Hyposulphite.

G. BOISSEL (*Presse Méd.*, May 17th, 1930, p. 670) in a series of cases reports several clinical facts about the useful therapeutic anaphylactic value of magnesium hyposulphite. Five cases of spasmodic coryza are quoted: two of classic hay fever, two without relation to the flowering season, and one a pastry-cook who, after several years, became very sensitive to flour—the last case described in detail. At first, four to six tablets, each of 0.5 gram, were given daily, but later 10 c.cm. of a 16 per cent. solution of the salt was injected intramuscularly. The results were very satisfactory and the conditions were greatly improved, although previous therapeutic methods had failed. Success has also attended treatment by magnesium hyposulphite in asthma, the crisis being relieved as rapidly as by adrenaline. It has also a preventive action, 10 c.cm. of a 10 per cent. solution being injected every four days, or even 2 or 3 grams being given by the mouth every twenty-four hours in some cases. Three other examples of successful results in skin disorders are described in detail, and it is also recommended for intractable vomiting in early pregnancy. The author discusses the therapeutic action of magnesium hyposulphite, and of the interaction of the salts of sodium and gold in tuberculosis, where his results have been relatively unfavourable.

156. Liver Treatment in Pernicious Anaemia.

H. M. CONNER (*Arch. Int. Med.*, May, 1930, p. 702) relates his experience at the Mayo Clinic in the successful treatment with an aqueous extract of liver of twenty patients suffering from pernicious anaemia. The extract was prepared according to the formula suggested by Porter, Williams, Forbes, and Irving in 1929, and during treatment the patients received regular hospital diet; beyond occasional diarrhoea no untoward symptoms were noted. A few days after starting the treatment the reticulated erythrocytes began to increase in number, reaching a peak from the third to the twelfth day; the increase, however, was not so great in those patients whose erythrocyte count was as low as 2,500,000 to 3,000,000 per c.mm. when the treatment was instituted. The initial dose was from 90 to 120 c.cm. daily, being reduced to half at the end of the first week; this was continued when the patient had returned home after twenty-four days in hospital, during which time the average erythrocyte increase was 1,500,000, or 437,500 for each week, being about the same as that obtained by liver diet. The reticulated erythrocytes increased to a maximum of 31.8 per cent. in one case, and their average highest percentage for all the cases was 12.5. The haemoglobin rose from an average of 36.9 to 63.3 per cent., the leucocytes from an average of 5,050 to 7,270 per c.mm., and the platelets from 151,800 to 202,500 per c.mm. The effect of the extract upon weakness, diarrhoea, sore tongue, paraesthesia, and gastric symptoms was similar to that noted during ordinary liver diet.

157. Treatment of Diabetes Mellitus.

N. B. FOSTER (*Journ. Amer. Med. Assoc.*, June 21st, 1930, p. 1971) remarks that with the advent of insulin the hope that the mortality from diabetes would show a definite decrease has not yet been realized; various reasons are ascribed for this. There is, he thinks, an astonishing fear in the medical profession of this remedy, which results in its being neglected often when it is indicated: another drawback is the too common unintelligent use of the drug. Acidosis is the special problem which arises sooner or later in diabetes; chemically its occurrence is due to the fact that so little dextrose is burned that fat combustion also is imperfect. Fatty acids, which are normally oxidized to carbon dioxide and water, oxidize in acidosis only to diacetic acids—the ketone stage. Two things are needed to control this abnormal fat oxidation: insulin, which will effect oxidation, and dextrose to be oxidized. The amount of insulin required is variable, but enough must be given. The urine should be tested every two hours during intensive treatment; if sugar appears, insulin should be used, but if it is absent dextrose may be given. The same principles govern the treatment of diabetic coma. Adequate amounts of insulin and dextrose should be administered, paying attention first to the acidosis, and letting the glycosuria wait. The dehydration of the patient must be also countered with saline solutions introduced by hypodermoclysis. The dose of insulin to administer cannot be fixed, and must be ascertained by trial. Foster discusses the reaction of diabetic subjects to physical exercise, and emphasizes the importance of obtaining the co-operation of the patient

in dieting, exercise, and taking insulin. In a second paper (*ibid.*, p. 1974) Foster deals with the question of foods and diets in diabetes. He shows that a maintenance diet is not necessarily adequate to the needs of active living, and may require adjustment. When the insulin dosage has been balanced, steps should be taken to ascertain if the diet meets the patient's normal demands; this can be determined by allowing him to continue his usual mode of life, with careful observation of his weight and strength. A basic fact in metabolism must be borne in mind when planning a reduction in diets. The patient's excess fat will decrease because it is called upon to supplement an inadequate diet. The patient is therefore actually on a high fat diet, and if acidosis is to be avoided the carbohydrates must not be too low, though the proportion of fat may be cut down to the minimum. In considering diets for children the requirements of growth must be also remembered. The author also discusses the problem of arterio-sclerosis complicating diabetes, and the special nourishment needed in pre-operative and post-operative periods is briefly indicated.

158. Palliative Intravenous Injections of Morphine.

H. JACOBAEUS (*Ugeskrift for Laeger*, April 3rd, 1930, p. 319) was induced to attempt relieving the pain of inoperable cancer some years ago by intravenous injections of morphine in a case in which he had found that even heroic hypodermic doses of morphine proved quite ineffective. The results were surprisingly good, and he now reports eight cases in which he has adopted this procedure with varying success. In a case of inoperable cancer of the uterus he gave 1.5 cg. morphine by intravenous injection at 10 a.m., and twice this dose by subcutaneous injection in the evening. The result was exactly the same every day: the patient was without pain and completely at rest till 6 or 7 p.m., and the subcutaneous injection was followed by a restful state during the first half of the night. In the course of the second half she became a little restless, and at 5 or 6 a.m. she had to have another subcutaneous injection of 3 cg. The effect of the intravenous injection was more rapid, complete, and lasting than the subcutaneous injection. In some instances the pain became less severe after the morphine had been given for a time by the intravenous route, and the author suggests that, after a time, morphine thus administered tends to reduce the brain's capacity for registering pain, at any rate for an appreciable period.

159. The Sulphocyanates in Hypertension.

J. F. BORG (*Minnesota Med.*, May, 1930, p. 293) is inclined to think that hypertension is due to spasm of the arterioles rather than to structural arterial changes; he considers that the action of the sulphocyanates in this condition has not yet been sufficiently explored. A series of 24 patients was treated by sulphocyanates, some being ambulatory; those in hospital were kept in bed for a week and given sodium bromide before treatment was begun. The starting dose was 2 grains thrice daily of sodium or potassium sulphocyanate, this being gradually increased after seven to ten days, if necessary, up to 10 grains; 12 of the 24 patients were suffering from symptoms referable to hypertension (headache, vertigo, etc.), 6 obtaining complete relief and 5 partial relief. The systolic blood pressure was reduced in 22 of the 24 cases (from 15 to 150 mm. Hg), and the diastolic pressure in 15 cases (usually more than 20 mm.), the maximum reduction occurring usually in about fourteen days. Toxic effects described are weakness, vertigo, erythema, and psychoses; although these are all of a temporary nature, they are of frequent occurrence (13 cases), and the author deprecates the use of sulphocyanate treatment unless the patient is under efficient observation and control.

Radiology.

160. Radiography in Recurring Dislocations of the Shoulder.

J. DIDIÉE (*Journ. de Radiol. et d'Electrol.*, April, 1930, p. 209) remarks that the exciting cause of recurring dislocations of the shoulder has been successively attributed to lesions of the musculature, then to lesions of the periarticular fibrous fasciculi, and, finally and more logically, to the skeleton itself; the alterations in the soft parts are the results rather than the cause of the recurrences. Such osseous alterations do not conform well with a theory of a purely traumatic pathogenesis, and the part played by traumatism in these dislocations is being gradually discounted. *X*-ray examination will reveal the type of abnormality present. Investigation of the shoulder, and especially of the humeral head, is a difficult matter, and without constantly keeping in mind the facts relating to the position of the arm, and in particular to its orientation, an exact and satisfactory interpretation cannot be made. The elements of the osseous surface which form the contours of the shadow differ according to this orientation, and ignorance of their position on the plate may give rise to serious errors. Two extreme orientations limit movements of the joint, external and internal rotation; they are not automatically produced by pronation and supination of the forearm. To determine them one landmark is useful, the epicondylar-epitrochlear axis (easily perceptible in all subjects), and the fixation of this axis into the space of the angle which it makes with the plane of the film permits of an exact precision. By varying this angle from 0 degree (axis parallel to the plate, external rotation) to 90 degrees (axis perpendicular to the plate, internal rotation) changes in the humeral head are shown, slightly apparent between 0 degree and 45 degrees and very marked between 45 degrees and 90 degrees. Didiée describes his technique in radiography of the shoulder, and adds that only by a minute analysis can a correct diagnosis and prognosis be made. This result must be obtained by a combination of the three incidences he describes, and which alone allows of making a complete survey of the epiphyseal mass and of omitting no detail. Two types of dislocation of the shoulder can be distinguished: one, of normal humeral heads, where violence alone explains the dislocation and the associated bony lesions; the other, of heads, primarily deformed, in which the trauma is less violent, and in which a complete or partial posterior notch is a possible factor in the recurrence.

161. Radiology of the Urinary Tract in Pregnancy.

FOR some years attempts have been made to discover chemical substances which will permit of the elective radiology of organs by injections into the general circulation, and Graham succeeded in rendering the gall-bladder visible by means of phthalein tetra-iodide. E. LEVY-SOLAL, J. DALSACE, V. MISRACHI, and I. SOLOMON (*Bull. Soc. d'Obstét. et de Gynecol. de Paris*, April, 1930, p. 228) state that such a substance with an elective urinary elimination is uroselectan, a 42 per cent. solution of a sodium salt of pyridine in iodine. The technique is as follows. In two injections separated by an interval of three minutes 100 c.cm. of a 40 per cent. solution of uroselectan are injected into a vein at the elbow. Radiographs are taken fifteen minutes, forty-five minutes, and one hour and a quarter after the injection. In normal cases about 90 per cent. of the product is eliminated in eight hours; at the end of that time the urine contains none of the solution, and the iodine is never found in a free state. Thus not only are excellent radiographs of the urinary tract obtained, but also some approximation of the renal functioning can be made. After the injection the urine contains a reducing body, which has yet to be studied. The advantages of this method, which is without any ill effects, are: the avoidance of the distension sometimes caused by pyelography and of an intervention which is occasionally traumatizing and delicate; particularly the obtaining of simultaneous bilateral examinations and the finding of anomalies not shown by pyelography; and its applicability in cases of impossible ureteral catheterization. Notes are recorded of the cases of two young pregnant women in which this procedure was advantageously employed.

162. Radiological Diagnosis of Intestinal Obstruction in Children.

FOLLOWING the observations made by Schwarz in 1911 G. WEBER (*Monats. f. Kinderheilk.*, May, 1930, p. 11) has examined radiologically a number of cases of intestinal obstruction, and finds that menisci between collections of fluid and gas stagnating in the loops of intestine proximal to the obstruction become visible if the rays fall parallel to the surface of the fluid collections, as is the case when the patient is screened standing up. Since it is not necessary to introduce any opaque fluid, the investigation only takes a few seconds, and does not entail any waste of time or risk to the patient. The method has been found particularly useful in distinguishing doubtful cases of intestinal obstruction in children from such conditions as acute enteritis. It is recommended that such cases should be screened thus without any preliminary enemata being given, since fluid retained from these may obscure the picture. The more extensive the collections of gas and menisci separating fluid and gas, the more probable is the diagnosis of an acute obstruction. A number of cases in which the clinical signs were obscure were diagnosed thus by positive radiograms, and the diagnosis was confirmed by operation. Weber points out, however, that no evidence of the nature of the obstruction is thus obtained, though in children the commonest cause is intussusception. If, however, an opaque fluid is administered subsequently, it is then sometimes possible to differentiate the rarer causes, such as bands and volvulus.

Obstetrics and Gynaecology.

163 Tuberculosis of the Vagina.

ALTHOUGH primary tuberculosis of the vulva and vagina is rare, owing to the resistance of the epithelial covering and especially to the horny layer, W. H. BATES (*Amer. Journ. of Surg.*, April, 1930, p. 810) maintains that its importance should not be overlooked. The pathology of this disease is shown by the appearance of one or more chronically inflamed indurated nodules in the vulva or vaginal wall. These may be separate or conglomerate, and may be ulcerated, with a slight discharge of sero-sanguineous pus which is usually not excessive. The edges of the ulcers are, as a rule, undermined, indurated, and irregular, with nodular bases which bleed only slightly when manipulated. Some of the tubercles may show excavation, while in other cases this is difficult to demonstrate. The inguinal glands in one or both groins are enlarged, and long-standing cases may show an extension of the tubercles into the adjoining tissues, particularly the perineum. The symptoms may be either local or general, depending on the degree of involvement. Pain may be absent, or may be present merely as a dull ache in the vulva and vagina. It is more severe in the pelvic and lumbar region when there is a pelvic involvement. There may be bleeding and oedema of the vulva, especially in children. These patients usually have poor appetites, and intermittent constipation and diarrhoea occur, with an intestinal involvement. Frequent urination with haematuria occurs when the urinary tract is involved, pulmonary involvement is attended with considerable coughing, and occasionally there is blood in the sputum, with night sweats. This condition must be differentiated from gonorrhoea, senile vaginitis, and ulcerative conditions due to trauma, prolapse, syphilis, and cancer, many tests, including biopsies and animal inoculations, are often necessary to establish the diagnosis. Most cases are complicated by tuberculous foci in other parts of the body, and the prognosis is exceedingly grave. Treatment has so far proved unsatisfactory. Medical measures are necessary in addition to rest, air, food, and sunshine. Surgery may be useful if the infecting focus is localized to a small area and the patient's health is not too poor, it is useless in disseminated cases. Cauterization should be considered in small areas of accessible foci.

164 Glandular Extracts in Uterine Inertia.

F. HOLTZ (*La Gynécol.*, March, 1930, p. 153) reports encouraging results from the use of thymophysin in primary and secondary uterine inertia. Thymophysin consists of a mixture of pituitary and thymus extracts, and was recommended by Lemesvary, it has been used since September, 1927, in 23 cases at Stockholm, and has been judged to be preferable to pituitary extract alone. A dose of 2 c.cm. has been found sometimes to occasion such strong uterine contraction that there is a danger of foetal asphyxia; the intramuscular injection recommended, therefore, is one of 1 to 1·5 c.cm., and the majority of the present author's cases received one dose only. Thymophysin was found to be effective in primary and secondary inertia, in the first and second stages of labour, and in premature as well as in full-time labour, it appeared to be useful also in one case of spontaneous abortion at the fifth month. It is said to be useless for induction of labour, and is contraindicated when strong uterine contractions or a marked increase of blood-pressure would be dangerous—for example, when there is foeto-pelvic disproportion, cardiopathy, renal disease, eclampsia, or the threat of uterine rupture.

165 Acute Diffuse Puerperal Peritonitis.

F. LANGELMANN (*Zentralbl. f. Gynäk.*, April 19th, 1930, p. 972) quotes from textbooks and the literature numerous statements that the prognosis in acute diffuse puerperal peritonitis is hopeless, or nearly so. In common with Leiser, however, he rejects such a pessimistic view, and records a series of 75 operations at Dortmund during six years, no fewer than 26 patients recovered. It is noted, however, that death occurred in each of 8 cases of post-partum peritonitis, in the remaining 67 cases of peritonitis after abortion there were 18 cases of streptococcal peritonitis with 12 recoveries, and 11 cases of peritonitis due to haemolytic streptococci with 6 recoveries. Among 13 cases of *B. coli* peritonitis the mortality was only 23 per cent. The 38 per cent. of recoveries in post-abortion cases is ascribed chiefly to early diagnosis and operation. As soon as peritoneal infection is suspected exploratory puncture of the pouch of Douglas is performed. If followed (if pus is obtained) by colpotomy drainage. If improvement does not result within a few hours a laparotomy follows, drainage being promoted in some cases by low counter-incision. Recently colpotomy in suspicious cases has been omitted, and at laparotomy (for this reason performed earlier) diffuse peritonitis is frequently found even when its clinical signs have been surprisingly insignificant. Langelmann holds that the drainage operation should be as simple as possible, to probe among the coils of intestine, or to explore the true pelvis from above in search of a localized abscess, is harmful. The diagnosis of puerperal peritonitis is dependent on spontaneous pain or tenderness in the upper abdominal zone; on increased muscular tension and on increasing abdominal girth. It may be assisted by puncture of the pouch of Douglas, or, as recommended by Bumm and Sigwart, of the abdominal wall. The leucocyte count is of little diagnostic aid.

166. Treatment of Salpingitis.

A. H. ALDRIDGE (*Amer. Journ. Obstet. and Gynecol.*, March, 1930, p. 381) reports an analysis of the operative results in 1,056 cases of salpingitis, and draws certain conclusions, classifying the operations as conservative or surgical according to the subsequent possibilities of future pregnancy. He considers that laparotomy is absolutely contraindicated for the cure of salpingitis while the infection is still active, a condition which can be diagnosed by the use of the sedimentation tests. Dangerous smouldering infections may persist in the pelvis unaccompanied by leucocytosis or pyrexia. Abdominal operations for active salpingitis are associated with an unjustifiable mortality, excessive morbidity, a high percentage of radical surgery, and disappointing sequels. When patients who have pelvic infections are subjected to long periods of convalescence and palliative treatment spontaneous cures occur not infrequently; should a subsequent operation become necessary the mortality and morbidity are appreciably lessened. Aldridge adds that drainage of the peritoneal cavity by the vaginal route is superior to other methods, since the period of post-operative morbidity from delayed wound union is materially decreased, as also is the incidence of post-operative incisional hernia.

167. Carcinoma of the Uterus treated by Radiotherapy.

H. M. MORAN (*Journ. of Cancer Research Committee of Univ. of Sydney*, February 1st, 1930, p. 215) publishes five recent cases of adenocarcinoma of the body of the uterus in which hysterectomy was contraindicated, and radiotherapeutic measures were consequently employed. He discusses the importance of early diagnosis, the radio-resistance and sensitivity of these tumours, the treatment of associated sepsis, and finally gives the technique and dosage, emphasizing the desirability of combining *x* ray with radium therapy. The total dosage must be calculated and, if possible, the two kinds of treatment should be continuous. A group of photomicrographs is given which show the progressive stages of the development of adenocarcinoma of the corpus uteri. The author concludes that where surgery is impossible or inadvisable radiotherapy is of definite value. Even where surgery is possible a preliminary four weeks' course of radiotherapy will probably minimize the risk from sepsis and cancer implantation. Post-operative irradiation is unlikely to be of much value after hysterectomy because an efficient dose cannot be delivered. The best technique comprises radium treatment, followed at once by deep *x* radiation.

168. Vaginal Antisepsis during Labour.

D. H. BESSESEN (*Minnesota Med.*, May, 1930, p. 318) urges the necessity of securing an efficient but mild antiseptic agent which could be applied to the perineum, vulva, and vaginal mucosa at intervals during parturition without causing tissue damage. He believes that in this way the number of infections during the puerperium could be reduced by half. H. Mayes paints the perineum with a 4 per cent. aqueous solution of mercurochrome, and rubs 4 c.cm. of this solution into the vaginal wall. Bessesen has been in the habit of painting the perineum with a 10 per cent. solution of mercurochrome, and introducing into the vagina a 5 per cent. solution of mercurochrome in glycerin, which also contains 1 per cent. iodine. He attributes a considerable reduction of morbidity in his obstetrical practice to this procedure.

169 A Post-climacteric Triad

H. C. GRAM (*Acta Med. Scandinavica*, April 22th, 1930, p. 139), who records sixty-nine illustrative cases, describes a triad consisting in adiposis dolorosa, arthritis deformans of the knee-joint, and arterial hypertension occurring in elderly women about the time of the climacteric. The subjective symptoms are vague rheumatic pains, pain in the knee, breathlessness, and palpitations. Multiparae seem to be specially predisposed. In a certain number of cases obesity and hypertension only, or obesity and arthritis of the knee-joints only, were found, and it was not until some years later that the triad was made complete.

Pathology.

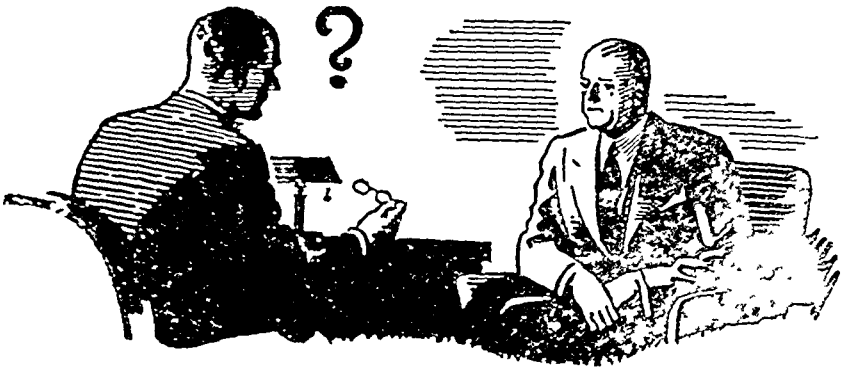
170. Vaccination against Cerebral Tetanus.

S. MUTERMILCH and Mlle E. SALAMON (*C. R. Soc. de Biologie*, May 9th, 1930, p. 23) adduce fresh experimental evidence bearing on the old question of immunity to cerebral tetanus. They find that vaccination of the rabbit by the meningeal route confers a marked resistance, enabling it to withstand the subsequent injection of toxin into the brain; they believe that this is due to the presence in the cerebro-spinal fluid of antitoxin which has been formed locally. If the rabbit is vaccinated by the subcutaneous route, or if it is passively immunized by the subcutaneous injection of serum, it does not prove resistant to intracerebral injection of toxin. But, as Descombey has shown, it is otherwise with the guinea-pig; by a single subcutaneous inoculation of anatoxin it is possible to protect this animal against the intracerebral injection of toxin five weeks later, though not with absolute regularity. The authors concluded that in the guinea-pig there must be some passage of antitoxin from the blood to the cerebro-spinal fluid. To ascertain how this occurred they tried the effect of injecting quantities of broth into the brain, such as would be used in the injection of toxin. They found that the effect of the broth was to set up an aseptic meningitis, which was accompanied by the passage of antitoxin from the blood to the cerebro-spinal fluid. The reaction varied in different guinea-pigs, and in rare cases was insignificant. In rabbits the meningeal reaction was less than in guinea-pigs. The authors conclude, therefore, that resistance to cerebral tetanus is dependent on the presence of antitoxin in the cerebro-spinal fluid; that in animals vaccinated by the meningeal route the antitoxin is formed locally and accumulates in the fluid; and that in guinea-pigs vaccinated subcutaneously, though not in rabbits, the intracerebral injection of toxin is followed by an aseptic meningitis, which enables serum antitoxin to pass into the spinal fluid.

171. The Etiology of Arthritis Deformans.

P. MOULONGUET and G. MIHAILESCO (*Presse Méd.*, April 2nd, 1930, p. 453) describe experiments supporting the view that the pulverization of the articular surfaces is a factor of great importance in the pathogenesis of arthropathies and arthritis deformans. They conducted three series of experiments on the knee-joint of rabbits. (1) Fine bone dust of other animals (cat, rat, rabbit), either obtained immediately after death, or killed by boiling, or dried and sterilized by the autoclave, was injected through a wide needle. (2) Bone dust was introduced by means of a spatula after arthrotomy. (3) The lower end of the femur was trephined with a bit after arthrotomy and the bony particles were pressed into the upper cul-de-sac of the articulation. The animals were examined on the fifth, tenth, and twentieth days. On the fifth day the particles were found to be deeply embedded in the synovial membrane. On the tenth day no particles could be found in the joint cavity; all had passed into the surrounding membrane, and microscopical examination revealed them being broken down rapidly by microphages. Certain fragments, however, appear to be being changed into masses of calcareous salts. On the twentieth day, and only in the arthotomy cases, it was found that another change was simultaneously taking place, there being a constructive reaction ending in the formation of osteophytes and articular foreign bodies. The microscopic appearance of these foreign bodies bears extremely close resemblance to the pathological findings of arthritis deformans. The nature of the origin of the introduced osseous particles was of no moment, suggesting that the important factor was the mineral base rather than the substance proper. The authors discuss the possible method of formation of the new foreign bodies, and point out certain implications as regards the surgery of joints; they advocate the employment of cutting or punching instruments in preference to rasps and saws. Illustrations are given of the injected particles in their various changing forms.

172. Experimental Work on Dengue Fever.



G. BLANC and J. CAMINOPETROS (*Ann. de l'Inst. Pasteur*, April, 1930, p. 367) give an account of experimental work during the epidemic of dengue at Athens in the autumn of 1927 and the summer of 1928. The serum of patients remained virulent, if kept in sealed tubes at 15 to 18° C., for at least 54 days. Evidence was obtained that man might become infected with the virus without developing symptoms of disease, and that this "inapparent infection" led to the development of immunity; during the course of the infection his blood was virulent for healthy volunteers. The guinea-pig inoculated with the blood of a dengue patient shows no pyrexia, but its blood becomes virulent for man five days later. Human volunteers inoculated subcutaneously with the ground-up bodies of *Aedes aegypti*, captured a week previously in the rooms of dengue patients, developed the disease seven to nine days later. Mosquitos of this species were able to transmit infection by biting; once they became infected, they remained so for practically the rest of their lives, provided they were kept at a temperature of 20 to 22° C. No evidence was obtained that *Culex pipiens* was able to transmit infection. The virus of dengue persists in the blood of patients for at least five days, and is infective for *Aedes*. Filtration experiments showed that in the body of the mosquito the virus was capable of passing through Chamberland L_2 and L_3 candles. Clinical experience indicated that one attack of dengue conferred immunity of considerable duration. Experimental evidence indicated that the serum of convalescent or recovered patients had no action on the virus, nor any prophylactic or curative effect in man. Successful vaccination experiments were, however, performed on a small number of volunteers by a first inoculation with virus treated with a 1 in 15 dilution of bile for five minutes, and a second inoculation a fortnight later with virus treated with bile diluted 1 in 20. Subjects vaccinated in this way withstood the subcutaneous injection of 2 c.cm. of virulent human serum.

173. The Distribution of Tubercle Bacilli after Tracheal Infection.

A. BOQUET, L. NÈGRE, and J. VALTIS (*C. R. Soc. de Biologie*, May 1st, 1930, p. 1227), using a very fine needle, injected 0.1 mg. of virulent bovine tubercle bacilli into the middle third of the trachea of 14 guinea-pigs. After varying intervals of time the animals were killed by bleeding, and 6 to 10 c.cm. of blood were injected subcutaneously into two normal guinea-pigs. Certain organs were removed aseptically, ground up in a mortar, suspended in saline solution, and injected into fresh guinea-pigs. It was found that the lungs and tracheo-bronchial glands were infective 30 minutes after tracheal inoculation, and that they remained infective continuously. The blood was infective after 30 minutes, negative after 90 minutes, positive after 7 hours, and then negative up to the end of a week, when it again became positive, and remained so. The spleen became positive after 7 hours, and remained so. It appears that the initial bacillaemia is very slight, and that the blood clears itself, remaining free from bacilli till a fresh invasion occurs from the developing lesions in the lungs and glands. In a second series of experiments a much smaller dose was used for tracheal inoculation—0.0001 mg. The results differed in some respects. The lungs were infective 30 minutes later, but the tracheo-bronchial glands did not become positive for 24 hours. The initial bacillaemia was not apparent; no organisms were detected in the blood for a fortnight. It is probable, however, that there was a slight bacillaemia shortly after infection, for the spleen was positive at 24 hours, though it subsequently became negative, remaining so till the end of a week. The authors consider that these experiments throw light on the mechanism by which tuberculosis of respiratory origin may become generalized, and explain how lesions in distal parts of the body may arise either soon after, or not for some considerable time after, the primary infection.

174. The Bacillus of Rhinoscleroma.

B. J. ELBERT and Mlle W. M. GUERKESS (*Ann. de l'Inst. Pasteur*, May, 1930, p. 548) have studied the properties of the organism described by Frisch in rhinoscleroma. This disease appears to be common in Russia and Poland, and has been encountered in several other parts of the world. Twice as many women are said to be attacked as men, and 70 per cent. of the patients are between the ages of 10 and 30. Several members of a family are often affected. The bacillus of Frisch can be recovered from the mucosa of the nose, pharynx, or larynx, and is present in the rhinoscleromatous infiltrations. The colonies on agar are round, convex, mucoid, with a mother-of-pearl tinge; they are opaque in the centre, and slightly translucent at the periphery. In broth there is a uniform turbidity, and often a mucoid surface pellicle. There is a nail-head growth in gelatin without liquefaction. Acid without gas is produced in glucose and sucrose, but not in lactose. The organism will not grow on agar containing 50 per cent. ox bile: no indol is produced. Colonies examined microscopically in the early stages of growth are said to have a characteristic appearance. These properties distinguish it from Friedländer's bacillus and from *Bact. aerogenes*. These three organisms can likewise be separated from each other by the absorption of agglutinins test. Whether these organisms, however, are distinct species, or only varieties of one and the same species, is doubtful. The authors have observed one strain of Frisch's bacillus, which after several months of cultivation in the laboratory took on the serological properties of *Bact. aerogenes*; and another strain which, though serologically identical with Frisch's bacillus, corresponded in other particulars with Friedländer's bacillus. Patients suffering from rhinoscleroma give a positive complement-fixation reaction with Frisch's bacillus, and agglutinate this organism to a titre of over 1 in 200.

The Answer to the "first Question"

INVARIABLY before prescribing for any ailment, the first question the physician asks the patient concerns the function of the bowels.

He then naturally asks himself what corrective, if any, to prescribe to suit the condition, without interfering with the treatment.

Agarol provides a safe answer to this.

Agarol Brand Compound the original mineral oil and agar-agar emulsion with phenolphthalein, is free from any artificial flavouring, sugar, alkali or alcohol. It is safe in diabetes, in gastric diseases, for children as well as adults. No excess of mineral oil to interfere with digestion or to cause leakage.

In addition, *gentle stimulation* of peristalsis, makes the result certain and the re-establishment of regular habits possible.

One tablespoonful at bedtime —is the adult dose.

Final decision on the true worth of Agarol Brand Compound rests with the physician. We will gladly send a liberal quantity with literature, for trial.

AGAROL BRAND COMPOUND *for Constipation*

FOR DEAFNESS

"ARDENTE" STETHOSCOPE.

Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting.

Doctors prefer "ARDENTE" because—

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises, giving inconspicuous hearing.
4. It conveys sounds from varying ranges and angles.
5. It is entirely different, unoppyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf through various causes.
7. It is helpful for conversation, music, talkies, wireless, home, office, public work, and sports.

FREE HOME TESTS
arranged for Doctors and Patients.
Medical Prescriptions made up to the minutest detail.

MEDICAL REPORTS.

Commended by all leading medical journals—Mr Dent will be happy to send full particulars and reprints on request

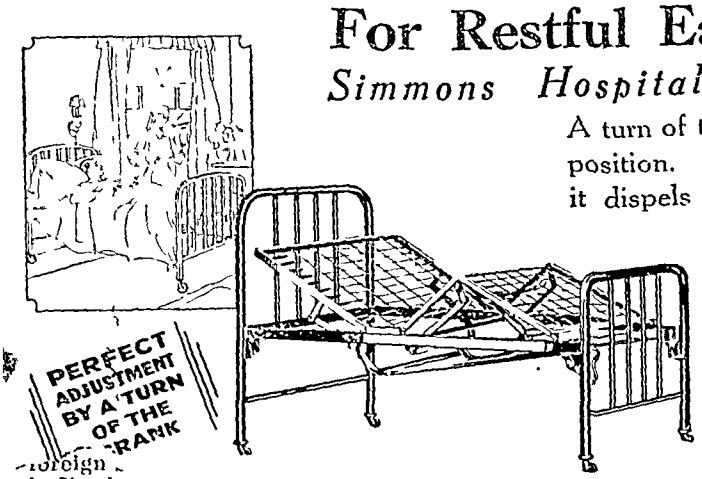
A HOSPITAL MATRON'S TESTIMONY.

"KORCET" Super Support Shoe, 26/9

Descriptive Booklet entitled "Foot Relief" on application.

"Nurse has been a different woman."

The following letter was recently received from the Matron of an important District Hospital:



"I feel I must write and thank you for taking so much trouble with Nurse S.'s feet. The 'Korcet' shoe has done wonders for her and enabled her to carry on with her work. She was getting so weary and ill that she was afraid she must give up. Since getting two pairs of 'Korcet' shoes she has been a different woman. There is another Nurse who needs special shoes—I will send her to you for 'Korcet' shoes."

There is an appropriate 'Korcet' shoe style for every degree of foot trouble.

Agents in all the principal towns.

KORCET SOFT TREAD SHOES

KORCET SHOE CO. LTD., Henry Street, Northampton.

For Restful Ease or Surgical Positions—

Simmons Hospital Beds are instantly adaptable

A turn of the crank adjusts the Simmons Bed into any desirable position. For convalescents this means maximum repose, for it dispels the necessity of constantly rearranging pillows.

The strong construction of Simmons Beds, and their hygienic qualities, make them invaluable to all Hospitals and Institutions.

NEURALGIA AND NEURITIS

Few diseases cause so much suffering as nerve pains, such as sciatica, trigeminal neuralgia, brachialgia, and intercostal neuralgia.

This group of diseases is rapidly and effectively treated at Pistany (Czechoslovakia) by volcanic mud—driven to the surface by hot sulphur springs. Statistics show that of 100 patients, only less than 5% do not respond to the treatment—30% are completely relieved and 65% are considerably improved.

Pistany RADIO-ACTIVE Mud Packs and Compresses are simply and easily applied. This treatment may be successfully combined with other physiotherapeutic methods.

August 6th, 1930.

THE MIDDLESEX HOSPITAL.

LONDON, W.1.

RADIUM TREATMENT OF MALIGNANT DISEASE.

Applications are invited from Medical Men interested in the Medical and Executive Radium Treatment, for a substantive post at this to be created. Previous experience essential.

For particulars of the duties of the post, and for details of the scheme of which it is a part, apply to the Secretary-Superintendent, Middlesex Hospital, W.1.

The Milroy Lectures on State MEDICINE AND PUBLIC HEALTH.

The Council of the Royal College of Physicians are prepared to receive applications for the office of MILROY LECTURER for 1932.

Applications must be addressed to the Registrar, Royal College of Physicians, Pall Mall East, S.W.1, on or before September 30th, 1930, and should contain a statement of the division of the subject selected by the candidate.

The course consists of Three Lectures.

The Lectures are to be given on Tuesdays and Thursdays in February or March, 1932.

A copy of Dr. Milroy's Suggestions on the subject of the bequest, and information as to the conditions, may be obtained from RAYMOND CRAWFURD, M.D., Registrar.

Guy's Hospital Dental School, London Bridge, S.E.1.

Applications are invited for the post of WHOLE-TIME TEACHER of CONSERVATIVE DENTAL SURGERY. The holder will act as Director of the Conservation Room and as Lecturer on Operative Dental Surgery. The appointment will be made for two years in the first instance, with eligibility for re-appointment thereafter. Salary at the rate of £1,000 per annum in the first instance. Further particulars with regard to the conditions, the status and prospects of the post may be obtained from the Dean, with whom applications (30 copies) should be lodged by September 15th. The applications should include a detailed statement of the applicants' previous experience and the names of two referees. Applicants must hold a qualification in Dental Surgery, registrable in the United Kingdom.

University of Manchester and MANCHESTER COMMITTEE ON CANCER.

JOINT COMMITTEE ON CANCER RESEARCH.

Applications are invited for a post as ASSISTANT in the Cancer Research Laboratories in the University. Experience in tissue culture research and bacteriology is required. Chemical experience also desirable. Salary £400 to £550 per annum according to qualifications and experience. Duties to commence September 29th. Applications must be submitted not later than September 7th to the Registrar, the University, Manchester, from whom further particulars can be obtained.

Birmingham and Midland HOSPITAL FOR WOMEN.

HOUSE SURGEON (man or woman) wanted for six months from October 1st next. Salary to be at the rate of £75 per annum. Applications, with copies of testimonials, to be sent to Mr. H. C. ASTON, 45, Newhall Street, not later than August 30th.

County of London.

APPOINTMENT OF CORONER.

The LONDON COUNTY COUNCIL invites applications for the appointment of a Coroner for the County of London. The salary attached to the office is £1,700 a year, inclusive, and it is probable that the selected candidate will be allocated to the prospective new northern district of the County. The Coroner will be required to provide the necessary office accommodation and clerical assistance and also defray all other expenses of the office, except actual disbursements under the approved schedule of fees, etc. Candidates, who must be not less than 35 or more than 50 years of age on January 1st, 1931, must possess both a legal and a medical qualification. Pensions are payable on retirement under an approved scale. The candidate elected must give an undertaking to give his whole time to the duties of his office. Due weight will be given to the claims of those applicants who served, or attempted to serve, with H.M. Forces during the war.

Applications must be made on the official form, a copy of which (with full particulars) may be obtained by sending a stamped addressed foolscap envelope to the Clerk of the Council, The County Hall, Westminster Bridge, S.E.1. Completed forms must be received by the Council not later than Friday, September 19th. Canvassing disqualifies.

MONTAGU H. COX,
Clerk of the London County Council.

The Royal Infirmary of EDINBURGH (1,010 Beds).

DEPARTMENT OF OPHTHALMOLOGY.

Applications are invited for the undermentioned appointments which will become vacant on October 1st.

(1) Combined post of SENIOR CLINICAL ASSISTANT and CLINICAL TUTOR (non-resident). Emoluments £145 per annum. Candidates must undertake to hold office for at least one year. Previous experience in Ophthalmic work essential.

(2) Which post is open to a Non-resident CLINICAL ASSISTANT. Emoluments £25 per annum. Candidates must undertake to hold office for at least one year. Previous experience in Ophthalmic work essential.

Both posts afford valuable experience to a Graduate intending to specialise in Ophthalmology.

Applications should be sent forthwith to the SUPERINTENDENT from whom further particulars may be obtained.

By Order of the Board of Managers,
HENRY MAW,
August 4th, 1930. Secretary & Treasurer.

City of Birmingham.

PUBLIC HEALTH DEPARTMENT, TUBERCULOSIS SECTION.

ASSISTANT MEDICAL OFFICER.

Applications are invited from single male Medical Practitioners for the post of Assistant Medical Officer. The successful candidate will be employed both in a Sanatorium and in a Dispensary.

The salary attached to the appointment is at the rate of £350 per annum, with Board, residence, laundry, and attendance, valued at £150 per annum. The officer appointed will be required to pay the Council all fees, allowances, and emoluments (other than the foregoing) received by him, and will be expected to join the Municipal Superannuation Scheme after medical examination.

Further particulars of the appointment and forms of application may be obtained from the Chief Clinical Tuberculosis Officer, 44a, Broad Street, Birmingham, to whom applications, stating age, experience, and qualifications, should be forwarded not later than August 29th.

The Council House, E. H. C. WILTSHIRE,
Birmingham. Town Clerk.

Royal Salop Infirmary, SHREWSBURY (150 Beds).

APPOINTMENT OF RESIDENT HOUSE SURGEON.

Applications are invited from fully qualified men for the appointment of Resident House Surgeon, vacant immediately.

Salary £160 per annum, with board, residence, etc. The appointment is for six months in the first instance, subject to re-appointment for a further period of six months.

Resident Staff comprises Resident Surgical Officer, House Physician, and House Surgeon.

Applications, in triplicate, stating age, qualifications, experience, nationality, and accompanied by copies of three recent testimonials, to be sent to the undersigned forthwith.

J. W. NOBLE,
August 11th, 1930. Secretary Supt.

County Council of Durham.

ASSISTANT WELFARE MEDICAL OFFICER.

The County Health Committee invite applications for the appointment of an Assistant Welfare Medical Officer (woman) at a commencing salary of £500 per annum, rising by annual increments of £25 to £700 per annum. Travelling expenses will be paid by the County Council according to scale.

The appointment will be held subject to three months' notice on either side, and to the following conditions:

(1) The officer appointed must be a registered Medical Practitioner between the ages of 25 and 45 years, must devote the whole of her time to the duties of the office, and must not engage in private practice.

(2) She should either have held a previous appointment as Medical Officer of an Antenatal Clinic, with the approval of the Minister of Health, or have had at least three years' experience in the practice of her profession and special experience of practical midwifery and antenatal work. The holding of a Diploma in Public Health, and practical experience in bacteriological laboratory work, will be deemed additional qualifications for the post.

(3) She will be subject to the directions of the County Medical Officer.

(4) She will be required to reside in Durham City, or such other place as required by the Council.

(5) She must be prepared, if called upon, to act as Locum Tenens to other Members of the Medical Staff of the County Medical Officer.

(6) The appointment will terminate on Marriage.

(7) The candidate appointed will be required to pass the County Council's medical examination, and will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

Applications, endorsed "Assistant Welfare Medical Officer," with copies of not more than three recent testimonials must be forwarded on or before 30th instant to the County Medical Officer, Shire Hall, Durham, from whom further particulars may be obtained.

Shire Hall, HAROLD JEVONS,
Durham. Clerk of the Council.
August 11th, 1930.

County Borough of Birkenhead.

PUBLIC ASSISTANCE COMMITTEE.

RESIDENT ASSISTANT MEDICAL OFFICER.

The Birkenhead Corporation invite applications for the appointment of Resident Assistant Medical Officer at the INFIRMARY, Tranmere, Birkenhead, which contains 600 beds.

Salary after the rate of £350 per annum, rising by annual increments of £25 to £450 per annum, together with the usual residential allowances.

The appointment is subject to the provisions of either the Local Government and Other Officers Superannuation Act, 1922, or the Poor Law Officers Superannuation Act, 1896, whichever is applicable to the successful candidate.

Candidates must be duly qualified and registered under the Medical Acts. The appointed candidate may be required, at the discretion of the Council, to undertake such other duties of a medical or surgical nature in the Public Health Services of the County Borough as may be assigned to him.

Further information may be obtained from the Medical Superintendent of the Infirmary.

Forms of application to be obtained from the Secretary, Public Assistance Offices, 3, Conway Street, Birkenhead, on receipt of a stamped addressed foolscap envelope, which must be returned to the undersigned not later than Saturday, August 30th, endorsed "R.A.M.O."

Canvassing the members, directly or indirectly, will disqualify any candidate.

E. W. TAME,
Town Hall, Town Clerk.
Birkenhead.
August 8th, 1930.

Chesterfield and North Derbyshire ROYAL HOSPITAL (190 Surgical and Medical Beds).

HOUSE SURGEON.

Applications are invited from duly qualified men for the above post, which becomes vacant on July 31st.

The appointment is for six months.

Salary is from £100 to £175 per annum, according to experience, with board, apartments, and laundry.

Applications, stating age, together with copies of three recent testimonials, should be sent to the undersigned.

G. SUNNUCK,
August 12th, 1930. Supt. & Secretary.

ROYAL AIR FORCE MEDICAL SERVICE

A limited number of candidates will be selected for COMMISSIONS as MEDICAL OFFICERS in the ROYAL AIR FORCE early in SEPTEMBER.

CONDITIONS OF APPOINTMENT.

Candidates will be selected after interview by a selection board without competitive examination.

They must be of pure European descent. They must be British Subjects, the sons of British Subjects and registered under the Medical Act.

Selected Candidates will be appointed to Short Service Commissions (for 3 years extendable to 5), and those under 28 years of age at the time of entry will be eligible for subsequent selection to Permanent Commissions, should they be desirous of remaining in the service.

Resident hospital appointments held since qualifying, will, under certain conditions, qualify candidates for antedate of commission; the age on entry to qualify for a Permanent Commission, if necessary, being increased by a period equal to the 'antedate.'

Excellent opportunities exist for clinical professional work, both Medical and Surgical, as well as for the study and practice of Hygiene, Pathology, Ophthalmology, and other special branches, adequate provision being made for permanent officers to attend Post-graduate courses of study.

OUTFIT ALLOWANCE.

An officer, who has not previously held a commission in H.M. Forces, will receive an outfit allowance of £50 on joining.

PAY, ALLOWANCES, PROMOTION, ETC.

The following table shows the current rates of PAY per annum for the various ranks.

IN ADDITION to pay, officers receive quarters, rations and attendance, or are given cash ALLOWANCES in lieu as shown in the table.

MARRIED OFFICERS who have attained the age of 30 YEARS receive either Married Quarters or ALLOWANCES at the MARRIED RATES.

Service	Rank	Pay	Allowances in lieu of Rations	
			Married	Single
On entry	Flying Officer	£405	—	£122
After 2 years on promotion to	Flight Lieut. ...	£441	£237	£192
Rising by increments after 2 and 4 years to	,, ,,	£702	£237	£192
After 10 years' total service on promotion to	Squadron Leader ...	£558	£237	£192
Rising by increments after 2, 4, 6, 8, and 10 years to	,, ,,	£849	£236	£192
By selection to ...	Wing Commander ..	£1,034	£237	£192
Rising by increments after 2 and 4 years to ...	,, ,, ...	£1,071	£237	£192
By selection to	Group Captain ...	£1,189	£309	£251
By selection to ...	Air Commodore ..	£1,357	£365	£312
By selection to ...	Air Vice Marshal .	£1,697	£429	£373

Rates of allowances abroad are fixed in relation to costs in the particular country.

The rates of pay of the Royal Air Force Medical Branch are fixed on an inclusive basis, and the fact that specialist pay and charge pay are not payable as separate emoluments was taken into account when the rates were fixed.

GRATUITIES.

Short service officers who complete their full period of service on the active list may be granted gratuity as follows on transfer to the reserve:

After 3 completed years .. £350.
After 5 completed years .. £700.

Permanent officers who are allowed to retire voluntarily before qualifying for retired pay may be granted gratuity as follows:

After 10 but less than 15 years' commissioned service .. £1,500.
After 15 or more than 15 years' commissioned service .. £2,500.

RETIRED PAY.

The current rates of service retired pay range from £455 a year, normally earned after 20 years' service, to £939 10s., the maximum for which an Air Vice-Marshal is eligible (at current rates).

Rates of retired pay are subject to alteration upwards or downwards within certain limits according to fluctuations in the cost of living.

Full particulars as to the conditions of service are contained in Air Ministry Pamphlet 25, a copy of which, together with form of application, can be obtained on application to the Secretary, Air Ministry (D.M.S.), Adastral House, Kingsway, LONDON, W.C.2.

Leicester Royal Infirmary.
(450 Beds)

HOUSE SURGEONS AND CASUALTY OFFICER

Vacancies are expected in the above offices on October 1st. Salaries at the rate of £125 per annum. Applicants must have held a Resident Hospital post, or had similar experience of Hospital work. Election about the middle of September for duty on October 1st.

Applications to the undersigned by Monday, September 1st.

HARRY JOHNSON,

Under the personal directorship of Dr. J. FIELD HALL and J. C. NEEDES

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

No charge is made to Principals for the introduction of Locum Tenens or Assistants.
Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. CHESHIRE.—Coast Town, within reach of Liverpool.—Well established PRACTICE, averaging over £1,200 p.a., including panel of 780. Fees from 3/6. Mid. 2 to 5 gns. Double-fronted house, with 3 reception, 4 bedrooms, etc. Price, freehold, £1,400, £800 on mortgage. Premium 1½ years' purchase, £1,100 down, and balance as arranged.
2. NORTH OF ENGLAND.—In a small pleasant town, old-established sound PRACTICE averaging over £1,200 p.a., including nearly £500 from panel and appts. Good house (3 reception, 5 bedrooms, bathroom, etc., electric light and every convenience, garage, garden). Price, freehold, £1,500. Mortgage for full amount can be arranged. Premium £1,450.
3. CROYDON AREA.—PARTNERSHIP.—A two fifths or one third share is offered in a well established and increasing middle class Practice, averaging £2,600 p.a. (last year £2,740). Panel of 935. Fees 3/6 to 21/. Midwifery 4 to 15 guineas. Choice of houses. Premium 2 years' purchase, part by arrangement.
4. DEVON.—VILLAGE PRACTICE, situated in very attractive district, within 5 miles of a Hospital town. Receipts for past 12 months £942, including panel producing about £230 p.a. Fees 2/6 to 10/6. Very good ten roomed house, with professional rooms, garage for two cars, cottage, etc. Large garden. Price for freehold £3,000, £2,000 on mortgage. Premium £1,500.
5. SOUTH-WEST OF ENGLAND, within ten miles of coast.—Steadily increasing Country PRACTICE in agricultural district, producing for the past 12 months over £2,300. Panel, with mileage, brings in over £400. Fees 5/6 to 21/-. House contains 2 reception, 5 bedrooms, etc. Garden. Garage. Rent on lease £50 p.a. Premium £2,800.
6. LONDON, S.W.—Riverside Suburb.—Old established non panel, non-dispensing PRACTICE, averaging about £1,400 p.a., with good scope. Fees 5/ to 10/6 and some at 21/-. Good corner house, with 7 bedrooms, etc., in excellent repair, on 54 years' lease (ground rent £19 p.a.), price £2,000, half on mortgage. Premium £2,000.
7. MANCHESTER.—Chiefly working class PRACTICE. Average income £1,000, including panel of 1,000. Moderate expenses. Corner house, with 3 reception, 8 bedrooms, etc. Garage. Rent on lease £65 p.a. Premium £1,500, or near offer.
8. NEAR HUDDERSFIELD.—PARTNERSHIP.—A half share in an old-established mixed class Practice. Income for immediate past year over £4,250. Panel of 3,500. Fees 3/6 to 7/6. Very good house, with 4 reception, 6 bedrooms, etc. 1½ acres of garden. Price for freehold £2,500. Premium 1½ years' purchase.
9. EASTERN COUNTIES.—Old established, unopposed, and rapidly increasing Country PRACTICE, in very pleasant sporting and agricultural district, averaging nearly £1,200 p.a. (last year over £1,400). Panel of 500. Very good house (3 sitting, 6 bedrooms, bathroom, etc.). Garden, with tennis lawn. Garage. Electric light. Price, freehold, £2,000, £700 on mortgage. Premium 1½ yrs.' pur.
10. EASTERN COUNTIES.—About 50 miles from London and within 10 miles of county town.—Old established PRACTICE in pretty country district for immediate disposal, Vendor having accepted an appointment. Receipts average nearly £900 p.a., including panel of 600, and Union £60. Nice house, with ample accommodation, garden, and garage. Can be bought or will be let. Premium 1½ years' purchase, part by instals.
11. PARTNERSHIP.—HOME COUNTY.—Within 40 miles of London.—In small village (with large surrounding population) in very pleasant district, the third share (with option to five twelfths in 3, and half in 5 years) of old estab. mixed class Practice, offering excellent scope. Present income £3,000 p.a., including panel producing over £1,200, and appt. worth £160. Visits 3/6 to 2 gns. Good house at moderate rental. Premium 2 years' purchase, cash. Good society and sport. Ingoing Partner should be about 30, English or Scotch, and married or about to become so.
12. YORKS.—In a clean and thriving manufacturing town, old-established non panel PRACTICE, partly Homœopathic, and held 50 years by Vendor who is retiring. Cash receipts average about £2,400 p.a. Patients better and middle class. Midwifery refused. Good house, rent £100 p.a. Premium only 1 year's purchase, part down and balance by arrangement.
13. DERBYSHIRE.—Good mixed class unopposed PRACTICE, in very picturesque surroundings, within easy reach of good town. Gross cash receipts for past twelve months £900, including panel of 476. Fees 3/6 to 7/6, medicine extra. Suitable house, with 2 reception, 5 bedrooms, etc. Half an acre of garden. Rent on lease £70. Excellent sport and schools. Premium £1,200 or near offer.
14. BORDERS OF BERKS AND HANTS.—In a delightful district, an old-established mixed class PRACTICE averaging for the past three years £904 p.a. (last year £973), including panel of 400. Visits 5/- to 12/6, medicine extra (3/6). One opponent. House contains ample accommodation (2 sitting rooms, 7 bedrooms, bathroom, etc.). Large garden and garage. Rent £50 p.a. Prem. £1,400. Excellent sport.
15. YORKSHIRE.—GOOD TOWN.—PARTNERSHIP.—A one-half share (guaranteed to produce £2,000 p.a. in first year) is offered in a good middle class PRACTICE. Income for the immediate past twelve months approximately £4,000. Small selected panel of 430. One appointment worth nearly £650 p.a. Fees 3/6 upwards. Opposition not strong. Suitable house can be bought or leased. Very good educational and sporting facilities. Premium 2 years' purchase.
16. NEAR HEREFORDSHIRE BORDER.—HOSPITAL TOWN.—Old established mainly good class non dispensing PRACTICE, averaging about £1,200 p.a. Panel of 500-600. Fees 5/- to 10/6. Nice house in centre of town. Price for freehold £1,200, part on mortgage. Premium £1,800, £1,500 down and balance by instalments. Up to date Cottage Hospital, and good scope for surgery.
17. YORKS.—PARTNERSHIP.—Within a few miles of large residential town, the half share of old established unopposed country PRACTICE, owing to retirement of senior partner through age and indifferent health. Cash receipts for past three years average over £2,500 p.a., including appointments and panel of 1,200. Very little midwifery. Railway station. Good house available, with large garden. Electric light and water laid on. Price freehold £1,200, part on mortgage. Premium 2 years' purchase.
18. PARTNERSHIP.—COUNTY TOWN, within 130 miles North of London.—A one fifth share is offered in a very old established good mixed-class Practice having good scope. Gross cash receipts for past twelve months nearly £6,000, including panel of 3,400. Fees from 4/-. Not much midwifery. Suitable house available. Prem. 2 yrs.' pur.
19. WEST OF ENGLAND.—In a small pleasantly situated town amidst beautiful surrounding country, old established PRACTICE. Income nearly £1,350 p.a., including panel of 900. Visits 5/- to 21/-. Little midwifery. Very attractive house in own grounds of 2 acres, 3 large professional rooms (separate entrance), 2 reception, 5 bedrooms, bathroom, etc. Vendor's freehold. Price £2,400 (£1,800 can remain on mortgage). Premium £2,000. Good society, etc.
20. PLEASANT CATHEDRAL CITY, within 200 miles North of London.—Old established mixed class PRACTICE, averaging £1,600 p.a., including £800 from panel and over £100 from clubs. Visits 5/- upwards (occasionally 2 gns.). Very little midwifery from 2 to 5 gns. large attractive house, with garden. Rent £80. Prem. 1½ yrs.' pur.
21. ESSEX.—Unopposed PRACTICE in very pleasant agricultural district, averaging £872 p.a., including panel of nearly 500, and appts. worth £140. Fees 3/6 to 10/6. Mid. 3 to 6 gns. (about 12 cases). Commodious house, with 2 reception, 5 bedrooms, and good professional accommodation. Large garden. Garage. Rent on lease £60. Good sport and schools within reach. Premium 1½ yrs.' pur.
22. LANCS.—Pleasant Town, near open country.—Well established middle- and better class PRACTICE. Cash receipts last year over £980, including panel of 900. Visits 3/6 to 7/6, medicine extra. Mid. 2 to 10 gns. (about 20 cases). Suitable house, with 2 reception, 4 bedrooms, etc. Price for leasehold £1,100, £600 on mortgage. Premium 1½ years' purchase, part by instalments.
23. GLOS. — COUNTRY PRACTICE. — Old established PRACTICE in picturesque surroundings, averaging about £1,250 p.a., including panel of over 1,100. Visits from 3/-. Commodious house, with 3 reception, 6 bedrooms, etc. Garden. Garage. Price for freehold £1,500, £1,000 on mortgage. Premium £1,850.
24. LONDON, SOUTH-WEST.—Very old established non-residential PRACTICE, averaging about £4,000 p.a. Panel of 1,500, but large scope for more. Fees 2/6 upwards. Suitable house or flat can easily be obtained to meet purchaser's requirements. Rent of surgery on long lease £100 p.a. Premium 1½ years' purchase.
25. LANCS.—LARGE TOWN.—Very old established good industrial class PRACTICE, producing £2,500 p.a., including panel of 1,804, and appts. worth about £120 p.a. Fees 2/6 upwards. Very suitable for two friends in partnership, as two houses available. Good sport and schools. Premium 1½ years' purchase. A one half share will be offered with view to succession in six or twelve months if desired.
26. SOMERSET COAST.—PARTNERSHIP.—In a small increasing seaside resort, the five twelfths share of a very old established PRACTICE, producing last year £1,600, but offering exceptional scope. Panel brings in £480, and appointments. Visits 5/- to 4 gns. Mid. 4 to 6 gns.; only about 12 cases yearly. Choice of 2 suitable houses (price freehold £950), with gardens. Electric light and gas. Premium 2 years' purchase.
27. SOUTH OF ENGLAND (Thriving Seaport Town, pop. over 30,000).—Old established mixed class PRACTICE. Income last year £623, but offering exceptional scope. Panel of about 430 and 2 small appts. Visits 3/6 to 5/-. Very attractive residence, with professional rooms, 2 reception, 4 bedrooms, bathroom, etc. Pretty garden. Garage. Rent on lease £100 p.a. Premium 1½ years' purchase.
28. KENT.—Pleasant Seaside and Residential Town (pop. 17,000).—Old-estab. non dispensing middle and working-class PRACTICE, averaging for the past 3 years over £1,050 p.a. including transferable appt. worth about £200 and panel of 500. Visits 3/6 to 10/6. House contains 8 rooms, kitchen, bathroom, etc. Garden. Garage. Price freehold £1,500, but might be rented. Premium £1,500.
29. MANCHESTER.—PRACTICE is situated in a growing district offering very large scope. Income about £1,700 p.a., including panel producing £430. Fees 3/6 upwards. Excellent detached house, well situated, with 3 reception, 5 bedrooms, etc., all in good order. Price £1,800. Premium 1½ years' purchase.
30. SURREY.—In a beautiful residential district within 40 miles of London (good train service) a small mixed class PRACTICE worth about £600 p.a. and offering scope. Select panel of 200. Charming house with ample accommodation in very pretty grounds (tennis court, etc.) of 1½ acres. Price, freehold, £3,500. Premium 1½ years' purchase.

Full Schedule of Terms and Conditions will be forwarded on application.

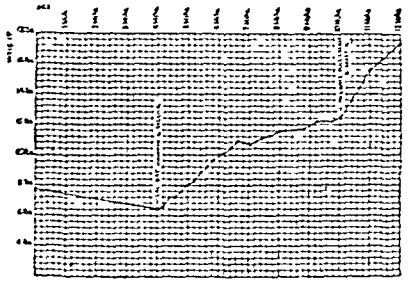
A "RESURRECTION"

.....GUILDFORD
30 6'30



"Baby Hook, came under my care shortly after birth suffering with marasmus following whooping cough. Broncho-pneumonia developed and was with great difficulty cleared up, leaving the child in a very low condition. Feeding proved a difficult problem, several things were tried without beneficial results. The results with Cow & Gate were truly wonderful, indeed it is a case of 'a resurrection.'"

(Signed).....M.B.Ch.B.

Lacidac (separated) and Brestol, the Cow & Gate Humanised Cream, were used in the early days of treatment. Cow & Gate Full Cream and Brestol being used subsequently.

BEFORE—4 months' old, 6 lbs. 9 ozs. in weight.

Progress Chart

AFTER—10 months' old, 12 lbs. 6 ozs. in weight.

June 1930. Baby Hook has now won a prize in a Baby Competition!

Write for literature and clinical samples of Lacidac and Brestol.

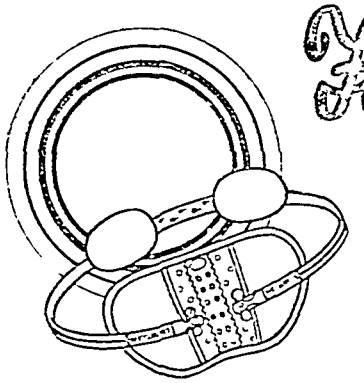
Students of Medicine

FOR the guidance and assistance of those wishing to enter the Medical Profession and for those already qualified who are desirous of planning a career there will be published, on

September 6th,

a



Special Educational Number

of the

British Medical Journal

THIS Number will contain full information regarding Medical Education and the fees charged by the teaching and examining bodies in England, Scotland, and Ireland. Details of the various Services and branches of specialist practice will also be included. The enlarged Advertisement Sections will contain much that is of value to the Student and Practitioner, and will certainly repay careful examination.

Announcement by the British Medical Association

For Summer wear

THE CURTIS 'SKELETON' SUPPORT WITH DETACHABLE COVERS IS IDEAL

Whilst being lighter and more hygienic than any other support on the market its efficiency is in no way impaired. The average weight for a person with a hip circumference of 32" is only 10ozs. All covering is detachable and washable and each appliance is supplied with a spare set of covers at an inclusive charge of £3 . 12 . 0

SALT'S (Patent) VARUS BOOT

WITH LEG INSTRUMENT

Over two thousand cases of Talipes Varus have been dealt with by us since we invented this Boot (all ordered through the Medical Profession)—and in every case our claim that it is a thorough corrective has been amply justified.

By use of this Appliance atrophy of Foot and shortening of Leg is avoided. In severe cases it is recommended that the Appliance be worn by night as well as day.

Note the Divided Construction

Medical Men are invited to write for our descriptive measurement forms, fill in required particulars, when a Boot will be made to their individual requirements.

SALT AND SON LTD.

ESTABLISHED 179?

A pure carbohydrate food

—that combats constipation, auto-intoxication and colitis

Lactose 73%, dextrin 25%—that is the proportion in which these carbohydrates are combined in this new food for changing the intestinal flora. Both are more slowly absorbed than other carbohydrates, and both are able to reach the colon in sufficient quantity to cause a luxuriant growth of protective flora. An acid reaction of the intestinal contents unfavourable to toxic organisms is thus produced—Lacto-Dextrin being highly efficient in promoting the growth and development of both B. acidophilus and B. bifidus in the colon. In this pure carbohydrate food both lactose and dextrin are presented in a palatable and agreeable combination.

PSYLLA

. . . an accessory for use in conjunction with Lacto-Dextrin

Where bulk and lubrication of the intestinal tract is also required, the use of Psylla (Plantago Psyllium) is invaluable as an accessory. The small brown seed when in contact with water swells into a soft gelatinous mass and acts most effectively both as an emollient and intestinal evacuant.

Samples and literature of both these intestinal products will be sent to members of the Medical Profession on request to Coates and Cooper, 41, Gt. Tower Street, London, E.C.3, Sole Distributing Agents for the United Kingdom and Irish Free State.

LACTO-DEXTRIN

Manufactured by the BATTLE CREEK FOOD CO., Mich., U.S.A.

READ THIS—

"I use your Ointment extensively for cases of Blepharitis of the eyelids, for Psoriasis, and for all skin diseases accompanied by itching. I always prescribe it with confidence. A bath at night with 15% Soap is certain relief for all forms of Pruritus. I use the same soap myself in the surgery for my hands preparatory to operating. I likewise use and frequently prescribe your shaving soap for patients suffering from Furunculosis or Acne of the face."

OLIVITA

OLIVE OIL WITH VITAMIN D

Olivita consists of the finest Virgin Olive Oil to which has been added that proportion of Irradiated Ergosterol which gives it a Vitamin D content equivalent to that of Cod Liver Oil.
Having investigated the conditions under which Boots Olive Oil is produced in Spain, the finest grade of Olive Oil available is guaranteed to be the first pressings from the Olives.
Olivita will be found very palatable and can be recommended without hesitation to regular users of Olive Oil.
The wide range of usefulness of Olive Oil is well known, and members of the medical profession will readily appreciate the further advantages conferred on this product by the incorporation of the sunshine Vitamin D.
Recent researches have indicated that substances containing Vitamin D should form part of the diet of all children during the period while the permanent teeth are being calcified. Cod Liver Oil is now often given to babies as a regular part of their diet as a good source of Vitamin D and Olivita provides a palatable alternative.
Its keeping properties have been thoroughly tested and the uniformity of its vitamin content is controlled by Biological tests.

OVALTINE

IN NEURASTHENIA.

Every potential neurasthenic is greatly assisted by liberal drinking of "Ovaltine." It is recommended as a between meals beverage or as a mid-day "light lunch," and it displaces tea or coffee with complete advantage.
"Ovaltine" is also invaluable when taken at the hour of sleep. Its use in this way has often avoided the need for employing hypnotic drugs.
The value of "Ovaltine" has been proved many times in such cases. It provides nourishment of the right kind, and in a form readily dealt with by the impaired digestive organs "Ovaltine permits of the liberal ingestion of food without taxing the digestive power.
"Ovaltine" is a complete natural food, yielding in one cupful a greater food value than three eggs. This delicious beverage is unquestionably a tonic nerve nutrient of a high order.

A liberal supply for clinical trial sent free on request.

Invaluable as a Galactagogue

This nourishing and sustaining food drink is helpful to nursing or expectant mothers

NOT only hundreds, but literally thousands of cases are recorded in which this well-known preparation — Horlick's Malted Milk — has proved its efficiency as a body-building food.

It is particularly valuable as an addition to the diet of the expectant and nursing mother. For Horlick's is a perfectly balanced food containing fat, proteins and soluble carbohydrates combined together in correct nutritive ratio. It is prepared from fresh, full-cream cows' milk, selected wheat and malted barley — and, during manufacture, is partially predigested to ensure easy assimilation.

Horlick's is rich in valuable malt-sugars, but contains neither cane sugar nor free starch. It is therefore extremely easily digested, and highly productive of energy.

These characteristics make it valuable as a galactagogue. Its abundant nutriment supplements any deficiencies in the mother's regular diet, and promotes a regular and nourishing supply of milk, and its easy digestibility makes it acceptable when other forms of nourishment are unwelcome.

Taken during pregnancy, it builds up the mother and helps to maintain her vitality. A cupful taken regularly first thing in the morning frequently abolishes and almost invariably alleviates the discomfort of morning sickness.

Horlick's is now obtainable in two forms — the original, natural-flavoured Malted Milk,. and the new Chocolate Flavoured form — identical in its constituents with the original Horlick's, but flavoured with fine chocolate. Horlick's is sold in sealed glass bottles, price 2/-, 3/6, 8/6, 15/-. Also in tablet form.

Further details may be obtained from Horlick's Malted Milk Co., Ltd., Slough, Bucks.

HOW GIBBS HELPS THE DOCTOR

Before Birth—in Childhood—for Men—for Women

Literally from the cradle to old age, Gibbs propaganda is reaching the vast majority of the British Public — teaching, reminding, exhorting—hammering home with untiring zeal, the great truths of dental prophylaxis as expounded by the Medical Profession and other authoritative bodies. It is interesting to note how closely all Gibbs propaganda echoes the utterances of the highest dental authorities.

Gibbs literature conveys authorised advice to many Mothers as to their diet before Baby is born. Then beginning with the "milk" teeth a continuous safe and sane stream of propaganda is maintained — reaching the child at all ages, until at last in manhood or womanhood he or she still finds that the truths they learned in Baby days are equally applicable to their grown-up years.

Gibbs Dentifrice claims to be a safe and sane mechanical cleanser with a beneficent chemical action on the mouth. Probably its greatest value to the Doctor is the sense of fastidious cleanness it creates in the user which makes anyone using Gibbs Dentifrice unwilling to allow any defective mouth condition to rest a moment untreated.

The best of all for all ages, Gibbs Dentifrice is itself the finest help the Doctor has.

GIBBS DENTURE TABLET

Gibbs new Denture Tablet is for cleaning Dental Plates, Bridgework (both gold and vulcanite) and artificial teeth. It gives a high polish, removes stains, makes plate or teeth sterile and antiseptic without in anyway injuring the softest gold or the finest vulcanite or platinum. The formula has been submitted to and approved by important members of the Medical Profession.

Gibbs Dentifrice

Literature, propaganda material, kinematograph films, leaflets, etc., are always freely at your disposal. Address: Dental Dept. 202WX, D. & W. Gibbs Ltd., London, E.1.

GD Dr 31

MALNUTRITION and MARASMUS

Mellin's Food has met with very remarkable success in the treatment of infants of retarded development due to nutritional disorders. Infants in this condition need a food substance that is assimilated quickly and one that may be taken in comparatively large amounts.

The carbohydrate maltose, which is the principal sugar in Mellin's Food, is a food substance that offers the greatest assistance in the adjustment of the diet because it yields immediately available nutrition and can be at once utilised to furnish the necessary heat and energy.

Mellin's Food

"MODIFIED MILK IN INFANT FEEDING"

The above-named booklet of 64 pages, which gives further information regarding the use of Mellin's Food in cases of malnutrition, will be gladly sent to Members of the Medical Profession.

MELLIN'S FOOD LTD., LONDON, S.E.15.

PUERPERAL MORTALITY

It is now considered that the majority of cases of puerperal sepsis are caused by the introduction of streptococci from without during the course of labour. This is a cause which should be preventable by the use of an efficient germicide.

The germicide in common use in obstetrics has been lysol, but it has been shown recently that the dilution of lysol which can be relied on to kill streptococci is far stronger than the tissues can stand.

Considerable advantages are afforded by the use of Monsol germicide, which is bland and emollient in action and, having 10 times the germicidal strength of lysol on streptococci, can be safely used at a strength which ensures the destruction of these bacteria.

In addition, Monsol has a particularly selective action on the strain Haemolyticus, which is considered one of the principal causative agents of puerperal sepsis.

Moreover, the presence of organic matter affects the germicidal action of Monsol much less than that of any other antiseptic known, while at therapeutic concentrations Monsol is absolutely non-irritant to mucous membranes.

MONSOL BRAND

Monsol Liquid for dressings, douches, packs, and all sick-room purposes.
Monsol Capsules, keratin-coated, for intestinal disinfection.
Monsol Ointment and *Monsol Throat Pastilles*.
Monsol Dental Cream, *Monsol Antiseptic Toilet Soap*.

"BYNO" HAEMOGLOBIN

A Powerful Hæmatinic and Tonic

Presents the hæmoglobin, proteins and salts of fresh blood in combination with "Bynin," Liquid Malt. The hæmoglobin is prepared by a special process which conserves its physical properties and prevents decomposition, an important point since decomposition is accompanied by loss of therapeutic properties.

Advantages of "Byno" Hæmoglobin over inorganic iron preparations are its rapid absorption, greater hæmatopoietic effect, and its freedom from gastro-intestinal disturbances.

Indicated as a routine treatment in simple anæmias, in general debility and in convalescence. Clinical trial samples and literature will be gladly sent on request

The "Allenburys"

"CHARKAOLIN"

GRANULES

"Charkaolin" is a highly efficient agent for the treatment of intestinal infections characterized by abnormal fermentation and the formation of toxins. It combines the absorbent properties of highly activated vegetable charcoal with the well-known toxin adsorbing qualities of "Osmo" Kaolin.

It is in the form of fine, clean granules which disintegrate rapidly in water and diffuse their ingredients evenly throughout the liquid. "Charkaolin" is tasteless, forms a fine suspension in water and is, therefore, quite easy to take.

Descriptive literature and a clinical trial sample will be sent on application

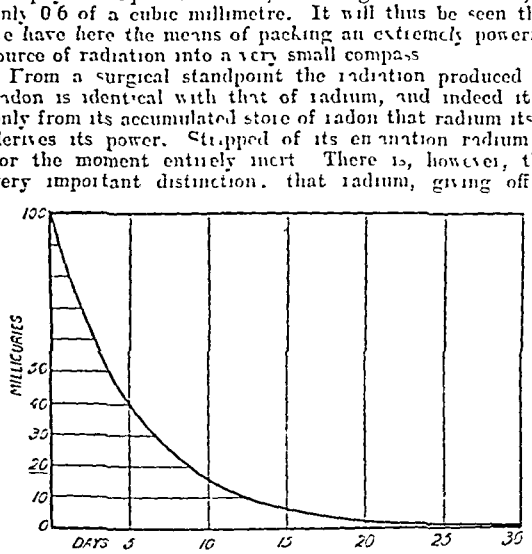
Observations on THE USE OF RADON SEEDS IN THE TREATMENT OF CARCINOMA.

BY



H. S. SOUTTAR, C.B.E., M.D., M.Ch., F.R.C.S.,

SURGEON TO THE LONDON HOSPITAL

THE use of radium emanation in the form of seeds presents very considerable advantages in practice, and for nearly two years I have adopted it whenever possible, to the exclusion of other methods. In the course of that time I have developed certain modifications in technique which I have found advantageous, and although it is obvious that observations on cases treated over so short a period can only be of a tentative nature, I feel that they may not be devoid of interest.

Radon, or radium emanation, is a heavy gas of atomic weight 222, and it is formed by the decay of radium at an absolutely constant rate, which is independent of the physical condition of the radium, its solution temperature, or pressure. Radon itself decays, but by the end of a *month, if undisturbed, the radium and its emanation have* virtually reached a state of equilibrium, when the production of radon is balanced by its decay and no further accumulation can take place. The amount of radon in equilibrium with one gram of radium is defined as one curie, and the volume of this very potent source of energy, the physical equivalent of 1,000 milligrams of radium, is only 0·6 of a cubic millimetre. It will thus be seen that we have here the means of packing an extremely powerful source of radiation into a very small compass.

From a surgical standpoint the radiation produced by radon is identical with that of radium, and indeed it is only from its accumulated store of radon that radium itself derives its power. Stripped of its emanation radium is for the moment entirely inert. There is, however, this very important distinction, that radium, giving off a

constant stream of radon gas, furnishes through this a constant and unvarying source of radiation, but radon, separated from its parent, steadily decays. Commencing with 100 millicuries of radon, we have left at the end of 3·82 days only 50 millicuries, in 9 days only 20, and at the end of a month practically the whole has gone. If, then, we use radon we must recognize that we are using a diminishing source, and make a corresponding allowance in the amount we apply.

This steady decay in power might be a fatal objection to the use of radon in surgery, but this is not in fact the case. All the evidence at present available goes to show that the effect produced upon a tumour is proportional to the total energy delivered, and that it is a matter of apparent indifference within certain limits whether this energy is produced slowly or rapidly, or whether its rate of production is constant or diminishing. It may, indeed, eventually prove that a powerful attack gradually withdrawn is more effective than a continuous bombardment at constant pressure.

It is usual to collect the radon in fine glass capillaries but these must be screened by metal sheaths to cut off beta rays which have no selective action on the cells of carcinoma and produce a general local necrosis of the tissues. The most effective screen is platinum, and with a platinum sheath whose wall is 0·3 mm. in thickness, all but a very small fraction of the beta rays are absorbed. I have found however, that with such small amounts of radon as are used in seeds—usually from 1 to 2 millicuries—silver of the same thickness forms a perfectly satisfactory screen at a fraction of the cost, whilst it is an old observation that silver, owing to its slight antiseptic properties, is better tolerated in the tissues if left in permanently. The only exception is in the case of a growth close to a mucous or cutaneous surface, and here platinum should be used, as these surfaces are peculiarly sensitive to beta rays. The seeds may be attached to fine silk threads to be removed, but personally I only adopt this course in such special regions as the eyelids. In most regions the seeds may be left in per*manently without any ill effect.* The seeds I use are of one standard size, 5 mm. in length and 1·1 mm. in diameter. The wall is 0·3 mm. in thickness, so that a lumen is left 0·5 mm. in diameter, allowing ample room for the glass capillary. The seeds contain 1, 1·5 or 2 millicuries of radon, and they may be inserted in large numbers. Thus for a breast case 50 × 2 mc. seeds would be used, unless the patient were very stout or very thin, or the tumour exceptionally large, in which case the number or strength of the seeds might be modified. In a tongue one might use 10 × 1·5 mc. (preferably platinum), but a similar or larger quantity might be required for secondary glands in the neck. In the œsophagus I should use 12 × 1·5 mc. seeds in an ordinary case, in the rectum perhaps 30 × 2 mc.

These examples will serve to show the adaptability of seeds to various conditions and the flexibility of these small standard units to meet varying requirements as to dosage. In general, the aim in view is to produce a near uniform radiation of the region under treatment by as accurate a "random" distribution as it is possible to obtain. It is obvious that the smaller the unit the more easy will it be to obtain a true "random" distribution. In such a distribution it is obvious that the effects of crossfire will be important, but it is not usually realized how considerable this effect may be.

It is a generally accepted standard of dosage that one millicurie of radon during its decay will produce a gamma radiation sufficient to destroy all carcinoma cells within a distance of 0·5 cm. This is of course a very rough estimate, for no account is taken of the considerable variation in the sensitivity of various types of cancer. Taking, however, as a rough basis of calculation it would be [illegible] that the correct dose would be 1 millicurie per cubic centimetre of tissue, 1 centimetre in diameter, and that a sphere 3 cm. in diameter would require 512 millicuries, since its volume is 512 times that of the unit sphere. Let us see how this estimate is affected by crossfire.

Let us represent the density of radiation at any point P by the letter R, taking as unity the density of radiation produced by 1 mg. of radium at a distance of 0·5 cm. Suppose the space around P to be filled by radium at a uniform density δ, so that every cubic centimetre of space contains δ milligrams of radium.

Consider a spherical shell described about P as centre, of radius r and thickness dr. The area of this shell is $4\pi r$, and its volume $4\pi r\,dr$, so that in this shell are contained $4\pi r^2 dr\,\delta$ *milligrams of radium*, all at a distance r from P. The density of radiation dR at the point P due to the spherical shell is proportional to this and to the inverse square of the distance, and we therefore have

$$dR = 4\pi r^2 dr\,\delta \times \frac{1}{4r^2}$$

since the radiation of 1 mg. at a distance of 0·5 cm. is taken as unity. Thus $dR = \pi\delta\,dr$, and hence on integration we have $R = \pi\delta r$.

In the case, then, of a spherical tumour of radius r and the density of radium required to [illegible] uniformly at the centre is given by $\delta = \frac{1}{4\pi r}$. The total radium required is therefore $\frac{1}{4\pi r} \times \frac{4}{3}\pi r^3 = \frac{r^2}{3}$.

If we are using radon the amount requ[illegible]

this has been followed by a rapid diminution in their size or even by total disappearance, and the fact that recurrence has in some instances occurred in more distant groups does not invalidate the local effectiveness of the seeds. It rather tends to show that the seeds must be distributed on a much wider scale, or that their action should be backed up by the more diffuse form of radiation which can be obtained from a collar.

The Breast

The breast is a site so easily accessible for the introduction of needles that it might be thought that seeds presented few advantages. This is, however, far from being the case. The seeds can be introduced through a few minute punctures, not more than six being required in even the most extensive case. With the introducer which I have described their distribution can be controlled with mathematical precision, and x-ray photographs have convinced me that they do not wander from their site in any reasonable time. The punctures through which they are introduced heal almost immediately, so that there is no possibility of sepsis to complicate the treatment whilst the patient is saved from the considerable annoyance caused by threads and the removal of needles.

The seeds are introduced according to the very satisfactory plan worked out by Gask and Keynes for the introduction of radium needles. The region just beyond the growing edge of the actual tumour itself is infiltrated with long columns of seeds, perhaps five rows with five seeds in each row, and above this into the base of the tumour itself further rows of seeds are inserted at right angles to the original set. Thus, the first layer of seeds will probably lie in the pectoral fascia, while the second lies in the substance of the tumour, assuming that the latter is of considerable dimensions. The cannula is now introduced through a puncture in the axilla and passed up beneath the pectoral muscles along the axillary vein, until it can be felt just below the middle of the clavicle. A long line of seven or eight seeds is now deposited, and this line is duplicated by another at a somewhat lower level, which really lies for the most part, in the pectoralis major. Through the same puncture a line of seeds can be introduced along the axillary border of the pectoralis minor and upon the surface of the serratus magnus just behind this. Finally separate seeds are introduced, one in each of the intercostal spaces just outside the sternum, and two into the sheath of the rectus.

Although this is the general arrangement of the seeds it may have to be modified to suit special circumstances. On occasions I have had to deal with tumours so large that I felt obliged to concentrate the whole of the seeds upon the tumour itself, leaving the lymphatic infiltration to a later date. One has to remember that the exposure of a patient to too large a dose may have serious constitutional results.

The Oesophagus

The treatment of carcinoma of the oesophagus by means of radium presents very considerable difficulties. There is the difficulty of obtaining access to the tumour, secondly of forming any estimate of its dimensions, and thirdly of introducing radium. The last difficulty is to a large extent overcome by the use of seeds, whilst access to the upper end of the tumour can be obtained fairly readily by a properly designed oesophagoscope. Some idea of the length of the tumour can be formed from a radiogram after the swallowing of a bismuth emulsion, but it must be admitted that it is impossible to form any but a very vague idea of the extent of the growth. It has been suggested that free access and more complete information would be gained by thoracotomy, but few of the patients with this disease are in a condition for such a formidable procedure, whilst there is so far no evidence to show that the results would be at all improved by its use.

My present method of procedure is as follows. Using the largest possible tube of my own oesophagoscope with proximal illumination, an excellent view of the upper end of the growth can be obtained. By means of a special introducer the seeds are passed down the lumen of the tube and implanted in the growth under the full control of vision.

The introducer consists of a short cannula carried at the end of a long wire, with a plunger which can be operated from the proximal end. Each seed is placed separately into the distal end of the introducer and secured with a little vaseline. The instrument is inserted into the growth, and on pushing home the plunger the seed is deposited. By deflecting the oesophagoscope in different directions, and by inserting the introducer to different depths the seeds may be deposited through the growth with much greater uniformity than might be imagined. About twelve seeds of 1·5 mc. each are inserted. There is no reaction but in about a week improvement in swallowing may be expected to commence and in a favourable case the patient should in three weeks be able to swallow ordinary soft food without difficulty.

This method of treatment has the advantage of simplicity and apparently of safety, for I have never so far seen any untoward result. An obvious criticism is that there is no guarantee that the seed will not be implanted in the mediastinum or elsewhere outside the growth. As however, it is impossible for organisms to grow in the neighbourhood of an active seed the risk is more apparent than real. The great advantage over intubation is that there is no need to pass a bougie through the lumen always a difficult and dangerous procedure.

The Rectum

The rectum is a region peculiarly adapted to the use of seeds, especially if the growth is situated within reach of the finger. In this case the growth itself and the whole of the pelvic tissues around it can be easily infiltrated with seeds through two small punctures in the perineum and the simplicity of the procedure and the absence of sepsis are then very valuable. I shall describe the method as it was applied with complete success to a carcinoma of the posterior wall of the ampulla in closing the sacrum. With the patient in the lithotomy position two small punctures were made in the perineum one on each side of the tip of the coccyx and thirty seeds of 2 mc. each were introduced in long columns so as to be deposited as uniformly as possible in and around the growth. The magazine introducer was used and its position was controlled by means of a finger in the rectum in contact with the growth. Care was taken to establish a substantial barrier of seeds in the hollow of the sacrum behind the rectum in order to irradiate both the base of the growth and the rectal glands.

presentation of actual cases is the only sound foundation upon which to build at the present time, for only in this way can the powers and the limitations of radium be shown.

The following notes have been suggested by a study of the cases, and express concisely the conclusions which may be drawn.

The Skin.—The skin is undoubtedly the most successful situation for the application of radium. Both basal and squamous carcinomas respond readily, and although in the former case the absence of secondary deposits is an advantage, this is somewhat balanced by a more marked tendency to local recurrence. Of the 11 cases under review, the tumour has disappeared in all, and there has been no recurrence, local or otherwise, after periods extending up to seventeen months.

The Lip.—In every instance there was a rapid local response, and 3 out of the 5 cases have remained well for six, thirteen, and fifteen months. The one fatal case was really untreatable when first seen.

The Tongue.—These were all advanced cases, untreatable by any other method. In every instance, however, there was a rapid local response, with, in every case but one, a total disappearance of the primary tumour. In the 4 cases where the glands were treated by radium they responded at once. In 5 of the 7 cases distant secondary deposits appeared, and in only one (21) is there any possibility of a permanent cure. This also was, however, a totally inoperable case.

The Mouth.—These were all entirely inoperable cases, 5 of a very advanced and extensive nature. In the only case where the growth was limited (26), although surgically inoperable, there has been no recurrence after two years. In 4 of the other cases the local growth disappeared, but recurred later. In 1 there was a local reaction of quite unexpected severity, masking the immediate effect upon the growth.

The Breast.—The 24 cases have been classed as early, advanced but operable, and inoperable. Of the 11 cases in the first group all but one have been followed up to date, and these all remain free from recurrence at periods of from six to twelve months. In 4 cases the tumour was first excised locally from doubts as to the diagnosis, but in the other 7 cases the disappearance of the tumour was entirely due to radium. Of 7 cases classed as advanced but operable, 1 was not traced, 1 was amputated after fifteen months for local recurrence, and 5 remain well after periods of from six to sixteen months. Of 6 cases which were totally inoperable, 1 died five months later from general dissemination, 1 remains locally well but has probably a thoracic deposit, and 4 remain well after periods of from six to eleven months. Out of 24 cases local recurrence has so far appeared in one case only. In 2 cases, however, the tumour did not respond, but in one of these removal of the tumour showed dense fibrosis with scattered groups of carcinoma cells.

SKIN.

No	Age and Sex.	Duration.	Characters of Growth.	Dosage.	Result.
1	F. 74	5 weeks	Small ulcer below outer canthus left eye. Squamous carcinoma.	2 × 2 mc.	Disappeared in 5 weeks. (9 months.)
2	M. 44	13 years	Circular ulcer 2 cm. diameter in front of left ear. Squamous carcinoma.	12 × 1.5 mc.	Disappeared in 4 months. (6 months.)
3	M. 67	42 years	Recurrent basal-celled carcinoma invading voluntary muscle of cheek.	4 × 1.5 mc.	Disappearance of local recurrence. (6 months.)
4	F. 68	6 months	Ulcer 2 cm. diameter outside external canthus right eye. Enlarged pre-auricular glands. Squamous carcinoma.	6 × 2 to ulcer; 7 × 2 pre-auricular glands; 7 × 2 upper cervical glands	Rapid healing of ulcer and disappearance of glands. (4 months.)
5	F. 63	10 months	Hard ulcerated mass size of pea upper margin left pinna. No secondary glands palpable.	2 × 2 mc.	Disappeared in 4 months. (17 months.)
6	M. 83	6 months	Ulcer 3 cm. diameter left cheek. Squamous carcinoma.	10 × 2 mc.	Disappeared in 1 month. (12 months.)
7	F. 61	14 years 6 months	Carcinoma of skin. Secondary in gland of groin.	14 × 2 mc into gland	Disappeared in 5 months. (9 months.)
8	M. 80	2 months	Ulcer 1 in. diameter behind left mastoid. No enlarged glands. Squamous epithelioma.	10 × 2 mc.	Rapid healing.
9	F. 79	Many years	Infected ulcerated mass 3 cm. diameter over left parietal region. Section: sebaceous carcinoma.	6 × 2 mc.	Complete healing in 4 months. (7 months.)
10	F. 76	7 years	Large vascular tumour 3 in. long, 1 in. wide, upper part of left neck reaching as high as the ear. No secondary glands. Probably a basal carcinoma.	15 × 2 mc.	Two months later tumour had entirely disappeared without ulceration. (5 months.)
11	M. 72	37 years	Extensive scarring from recurrent rodent ulcer. Nodule in left lower eyelid, one year.	2 × 1.5 mc.	Perfect result locally. (2 years.)

LIP.

No	Age	Duration	Characters of Growth.	Dosage.	Result
12	68	12 months	Huge fungating growth 4 in. × 2 in. with indurated base completely replacing lower lip and extending almost to point of chin. Squamous carcinoma.	32 mg., radium 5 days	Rapid disappearance of growth and reappearance of lip. Death after 10 months from secondaries in lungs.
13	61	6 months	Typical epitheliomatous growth 1 in. diameter in centre of lower lip.	5 × 1.5 mc.	Healed in 8 weeks. (15 months.)
14	47	9 months	Indurated ulcer 2 cm. diameter just above upper lip on right side. Section: squamous carcinoma.	12 mg., radium 5 days	Healed in 10 weeks. (13 months.)
15	68	8 months	Fungating epithelioma 3 × 1 cm. on right side of lower lip.	10 × 1.5 mc.	Healed in 4 months. (6 months.)
16	86	5 months	Fungating epithelioma in centre of lower lip.	8 × 2 mc.	Rapid disappearance of growth.

TONGUE.

17		12 months	Extensive leukoplakia with deep carcinomatous ulcer on dorsum, extending to epiglottis. Fixation and swelling of tongue. Secondary glands on both sides.	9 mg. radium 16 days	Ulcer disappeared and tongue became mobile. Healing complete in 6 weeks. Glands removed later. Died 4 months, distant secondaries.
18	49	3 months	Tumour involving whole of left side of tongue. Deep ulceration and complete fixation. Secondary glands beneath jaw.	30 mg. radium 6 days, tongue and glands	Rapid disappearance of tumour and healing of ulcer. Died 2 months, distant secondaries.
19	70	12 months	Deeply ulcerated carcinoma occupying posterior half of right side of tongue and extending to epiglottis. Glands in neck. Squamous carcinoma.	8 × 1.5 mc.	Rapid local improvement. Glands removed later and 8 × 1.5 mc. inserted. Died 6 months, distant secondaries.
20			Large ulcer on right side of tongue, extending to epiglottis. Glands in anterior triangle. Squamous carcinoma.	21 mg. radium 5 days	Rapid healing of ulcer. 8 months later new carcinoma on left tip of tongue, 8 × 1.5 mc. Healed but recurred. Died 11 months, distant secondaries.
21			Ulcer on left side of posterior surface of tongue extending to epiglottis and on to the fauces. Carcinoma, not squamous. Glands behind right border of tongue and floor in angle of jaw. Squamous carcinoma.	20 × 1.5 mc tongue and glands	Rapid disappearance of ulcer and of glands. Well after 8 months.
22				12 × 2 mc. tongue 28 mg. radium 6 days glands and floor of mouth 12 × 2 mc.	Rapid healing of tongue and disappearance of glands. Recurrence after 5 months in more distant glands. No recurrence in tongue or glands. Three months later cavity persisted. Radon again inserted. After 9 months no evidence of carcinoma in tongue. Secondaries in glands dissected out.

The cases show that, as a rule, carcinoma of the breast readily responds to radium, both in the primary tumour and in secondary deposits. In inoperable cases brilliant local results may be expected but as in these cases the ultimate outlook depends on the existence of secondary deposits, local disappearance must not be interpreted as cure. In operable cases we feel that the results so far obtained justify the use of radium by the method we have indicated. In these cases, however, it is of the utmost importance that they should be kept under the closest observation so that any recurrence may receive immediate attention. The treatment of carcinoma of the breast by radium must at present be regarded as in the experimental stage although personally we regard the experiment as a very hopeful one.

The Oesophagus.—Carcinoma of the oesophagus is at the present time and perhaps essentially an incurable condition and one can only aim at enabling the patient to swallow. The 20 cases here reported show beyond question that in a large proportion of cases this can be achieved by means of radium giving relief for periods up to fourteen months. In 15 of these cases the relief was such that the patient could swallow soft solids with ease and in 4 he returned to an almost normal condition. In 5 other cases there was definite improvement. There is thus no doubt that carcinoma of the oesophagus responds readily to radium introduced by the technique. We may have been unduly cautious in dosage, but those who are familiar with the direct examination of these cases will realize the risks involved. We can happily claim that no untoward event has followed on the operation in any instance so that in skilled hands the method would appear to be reasonably safe.

Various Sites.—These were all experiments in otherwise hopeless cases. In 3 however, there was very striking improvement and relief over a long period. In many ways Cases 81 and 82 showed the most remarkable results in the whole series, although followed later by secondary deposits. In the case of carcinoma of the rectum the tumour has entirely disappeared and the patient is *in perfect health after sixteen months.*

THROMBO-ANGIITIS OBLITERANS IN NON-HEBREW SUBJECTS, AND REPORT OF A CASE OF CHRONIC ULCUS CRURIS IN A YOUNG MAN.

BY

F. PARKES WEBER, M.D., F.R.C.P.,

H. RAST, M.D., M.R.C.S.,

AND

O. LUTTEROTTI, M.D.,

GERMAN HOSPITAL, LONDON.

A CONSIDERABLE proportion of cases of thrombo-angiitis obliterans have been reported during recent years as occurring in Great Britain and Ireland, in English, or at least non-Hebrew, families.* The following men were recently almost simultaneously in patients at the German Hospital, and their symptoms present certain special points of interest. The first two are certain cases, the third one is altogether doubtful.

CASE I.

An Englishman (no Hebrew ancestry), aged 22 years, was admitted on July 24th, 1929, on account of cyanotic discoloration of the region of the left great toe, and pain and symptoms typical of thrombo-angiitis obliterans dating from January 1928. In other respects the patient appeared healthy, and his Wassermann reaction was negative. From the age of 16 he had been accustomed to smoke cigarettes up to twenty daily.

On September 7th, 1929, a modification of periarterial sympathectomy was performed on the left thigh by Mr. Wright during Mr. Rast's absence. The operation was followed by an immediate rise in the superficial temperature of the affected limb and by diminution of pain, but the improvement was not lasting, nor was the result of diathermy really satisfactory. Although slight "mummification" developed at the tip of the left great toe the condition is now rather better than worse, and amputation has not yet been resorted to. The clinical picture is the typical one seen by us in Hebrew cases, but the patient's age is younger than that of most Hebrew sufferers. Though the local condition in this case is very bad it was almost as bad for a long while in one of the earliest of Dr. Weber's Jewish cases of the kind—a man who is still living and has all his limbs.*

CASE II.

An English assistant in a drug factory without any Hebrew or foreign ancestry, and aged 33, was admitted on June 1st, 1929, with a large chronic deep ulcer, like a tabetic perforating or pressure ulcer, about the size of a penny at the back of the right heel. This had started as a mere crack in the thick skin in February, 1928, and had gradually enlarged since then so far as the patient himself knew there had been no traumatic or other cause for its commencement. He complained of pain in his right heel and right calf with that of a toothache. For about six month before the appearance of the ulcer there had been pains in the calf of the right leg on walking, these were of the usual intermittent claudication type as in typical Hebrew cases of thrombo-angiitis obliterans. The patient had been a great smoker in the army during the war. Before the commencement of the ulcer there had likewise been attacks of pallor and numbness in the toes of the right foot, but otherwise the patient had enjoyed good health.

No pulsation was felt in either arteria dorsalis pedis. Apart from the thrombo-angiitis obliterans we found no abnormal symptoms by examination of the thoracic and abdominal viscera, the nervous system, the eyes, and the blood and urine. The brachial blood pressure was 135/75 mm. Hg. The Wassermann reaction was negative. The knee-jerks were rather active. Warm weather somewhat lessened the pain. On July 9th, 1929, Dr. A. P. Cawadias examined the patient's limbs with Pachon's oscillometer, and found the oscillometric index as follows:

	Right side	Left side
Calf of leg	0	1
Thigh	6	6
Upper arm	5½	5

Both legs therefore showed arterial sclerosis.

After treatment by insulin and other methods—following upon periarterial sympathectomy on August 30th—had been tried in vain, Mr. Rast resorted to amputation of the right leg on September 14th, owing to gangrene in the stump after an amputation had to be performed on September 21st through the middle of the thigh. The patient left the hospital on October 12th in good condition, *though he still had a little pain in the amputated limb.* Since then he is reported to have been doing well. On macroscopic and microscopic examination of the parts from both amputations the arteria tibialis anterior seemed normal, but the arteria tibialis posterior appeared to be rather small and was blocked by a canalized thrombus. The popliteal artery removed at the second amputation was blocked by more recent partly organized thrombus.

In this case the deep ulcer at the heel was an unusual early symptom in thrombo-angiitis obliterans. In the hospital at the same time with this patient was a somewhat older man, aged 50, complaining of a chronic calf ulcer under the left great toe, but his blood-serum gave a strongly positive Wassermann reaction, and mercurial treatment led to an excellent result. It is interesting that in the older man the pulsation in the arteries of the feet on both sides was excellent and by Pachon's oscillometer Dr. A. P. Cawadias found the oscillometric index at the right calf to be 4 against 5 at the left calf, so that the chronic ulcer in the left foot had not caused blood-supply on the left side and had only the oscillometric index somewhat greater than the left than on the right leg.

CASE III.

An Englishman, aged 25 years (without any Hebrew ancestry), was admitted on May 21st, 1928, on account of an indolent chronic ulcer on the left leg with much pigmentation in the neighbourhood on the outer leg. He had similar pigmentation and scars of previous ulcers. He said he had never had anything definite of varicose veins, and the leg ulcer had started after an attack of pneumonia about the winter 1925–26. He was of slender build and rather pale, but otherwise apparently healthy. He smoked and that he had been accustomed to smoke about twelve cigarettes daily since the age of 16. There was nothing special in the family history except that his father had suffered from chronic ulcers on both legs for thirty years before his death at the age of 66. Examination of the thorax and abdominal viscera, the nervous system, eyes, urine and blood revealed nothing abnormal, but the Wassermann reaction was positive. A periarterial sympathectomy on the left thigh in February, 1929, at the hospital had done no good.

After prolonged rest in bed and the ordinary methods of treatment Mr. Rast finally performed

* See, for instance, Telford and Stopford, *British Medical Journal*, 1924, ii, p. 1025; Sir W. J. de Courcy Wheeler, *ibid.*, 1927, i, p. 265; Iarnoch and MacRae, *Journ. the end of the transfusion the patient's face began to swell, and for ten minutes I was almost afraid to look at him, as the swelling continued. There were no other symptoms or signs; adrenaline, which was given at once, probably prevented more serious complications, such as oedema of the lungs or glottis. It was ten hours before the face was normal, yet at no time did the patient feel backache, dyspnoea, or shivering, while the pulse remained between 70 and 75 per minute.

Some physicians are of the opinion that there is more danger in giving a blood transfusion to a patient with pernicious anaemia than to patients with other forms of anaemia. I have noticed slight reactions quite as often in other types of anaemia; so far from being a dangerous proceeding, blood transfusion is practically devoid of risk if the grouping is correct, and it is often a life-saving measure.

After a transfusion there is frequently an immediate rise of temperature. This rise occurs in spite of using a donor of the same group as the patient, the temperature quickly falling to its usual height or to a lower level. In most cases of pernicious anaemia, when the patient has been running a temperature, there is a decided tendency for it to fall during the succeeding days and for a general improvement to set in, with an increase in the haemoglobin and in the number of red blood corpuscles, but this is not always the case, as will be shown later.

In severe cases of pernicious anaemia, with a low haemoglobin percentage and red blood cell count, it may happen that in spite of liver treatment no improvement takes place or improvement is very slow. This applies to raw liver, cooked liver, and to at least three varieties of liver extracts on the market. This poor response to liver is most noticeable when the patient is very anaemic and has a temperature above 100° F., and where the outlook is unfavourable or at any rate alarming. It is to this type of case that I wish to direct attention, for the results of a timely blood transfusion in these cases may be excellent.

The first three cases, described below, will bring out the points I wish to emphasize.

CASE I.

A woman, aged 49, had been in ill-health for over a year. Three weeks before I saw her she had become very anaemic; examination indicated a typical case of pernicious anaemia. The blood count was as follows: red blood cells 1,250,000 per c.mm.; haemoglobin 30 per cent. The temperature was 100° F.; faintness followed the slightest exertion.

Treatment was started at home, and she was admitted to hospital on the following day. She was given daily half a pound of whole liver, and liver extract equivalent to half a pound of liver; in addition liquor arsenicalis was prescribed for her. The temperature (Chart 1) became higher and higher on each succeeding day. Six days after beginning treatment her condition

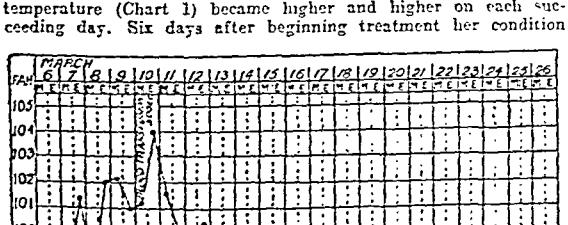

CHART 1.

was far worse than on admission. The red blood cells were then 1,000,000 per c.mm., and the haemoglobin 26 per cent. A transfusion of 500 c.cm. of blood was given, and improvement, it will be seen, set in forthwith, the temperature falling. A week after the transfusion the blood count was: red blood cells 1,800,000 per c.mm.; haemoglobin 40 per cent. Two weeks after this the red blood cells were 3,290,000 per c.mm.; haemoglobin 63 per cent.

A more typical and less dramatic case is the following one.

CASE II.

A man, aged 32, was admitted in a more or less desperate condition. A diagnosis of malignant endocarditis was made from the presence of haemic murmurs and a high temperature. The blood count was as follows: red blood cells 830,000 per c.mm.; haemoglobin 26 per cent.; the average diameter of the red blood cells was 7.8 μ.

He was put on whole liver, half a pound daily, and liquor arsenicalis, but his condition did not improve; during the first five days of liver treatment his temperature became higher (Chart 2). He was delirious at night, and in his lucid moments complained of feeling light-headed. He was given a transfusion of 600 c.cm. of blood, and his temperature then began to fall. His general condition improved, but he was still mildly delirious

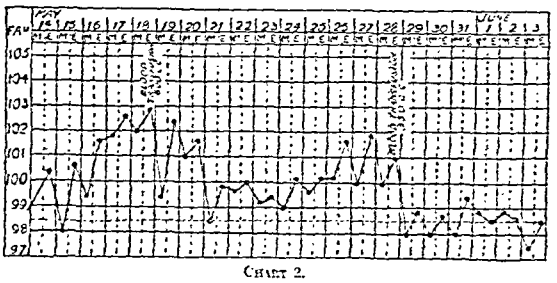

CHART 2.

at night. The blood picture was as follows: red blood cells 1,450,000 per c.mm.: haemoglobin 32 per cent.

This condition persisted for a further ten days. At the end of this period he was still running a temperature, which tended to become higher, in spite of the fact that he had had raw liver for fifteen days. A blood count at this stage was as follows: red blood cells 1,560,000 per c.mm.; haemoglobin 33 per cent.

At this point a second blood transfusion was given; after this he began to make good progress, the temperature gradually falling, with distinct improvement in the blood picture. A blood count taken a week later showed the red blood cells to be 3,400,000 per c.mm. He was discharged two weeks later, and was able to get about perfectly well.

CASE III.

A woman, aged 46, was treated with liver for pernicious anaemia, and told to continue taking this in the form of liver extract. For a few weeks she did as she had been advised, but after this apparently she did not take it regularly, until about a year later, when she began to feel weak and noticed that she was again becoming anaemic. When I examined her I was told that she had taken the equivalent of a quarter of a pound of liver daily as extract for the past three weeks. She was mildly delirious at times, but a more alarming sign was persistent dyspnoea. The practitioner who attended her told me that her temperature had kept between 101° and 102.5° F. for several days. The red blood cells were 1,300,000 per c.mm.; haemoglobin 28 per cent.; but from her general condition a fatal issue seemed certain. From that day she received arsenic and half a pound of raw liver daily, and on the next day I gave her a transfusion of 500 c.cm. During the next four days there was a decided tendency for the temperature to fall, and, although this was followed by a rise, the temperature was normal at the end of ten days, and the patient was convalescent in two weeks.

It may be contended that these three patients—and others similarly affected to whom I gave blood transfusions—would have improved on liver alone if left sufficient time, but I was not prepared to run any risks, as I have seen four patients that have died who were given liver and arsenic, and in three of these four blood transfusion had been performed by me. Patients without pernicious anaemia, the red blood cell count was above 1,500,000 per c.mm., were never given blood transfusions, and I think they surely improved on whole liver. I do not wish, however, to convey the impression that a blood transfusion is essential for all patients with a low red blood cell count, and I admit that even those with a high rise of temperature may possibly weather the storm, but the risk appears to me to be great.

Of the four cases that died, one was the Group I patient referred to above, who died eight hours after the transfusion. Of the remaining three cases, two were given liver extract and no whole liver, as it was thought that they would be unable to take the necessary amount of whole liver, and it was hoped that the extract would be of equal benefit. One of these received a blood transfusion of 600 c.cm., the other received two transfusions of 500 c.cm. on each occasion. The fourth patient was not given a transfusion, as she was our first case of pernicious anaemia to receive liver, but she vomited repeatedly, and this probably accelerated her death.

of liver extract was given. The injections were repeated two and four days later respectively.

On March 15th the condition of the child showed definite but slight improvement. Teaspoonful doses of liver extract were tried by the mouth and were retained. Two more injections of spleen and liver were given at two-day intervals and then the injection of liver extract was stopped but the injections of plasma were continued at four-day intervals until it had been given. The dose of the liver extract given by the mouth was gradually increased until two teaspoonfuls of the liquid extract were being taken three times a day. The child continued to make rapid and uninterrupted progress.

On April 30th she was looking very well and was up and running about. All physical signs including all traces of the cardiac murmur had disappeared. The liver extract by the mouth had been raised ten days previously to two teaspoonfuls (twice a day). A blood count performed on April 30th showed haemoglobin 82 per cent., red cells 6,330,000 per c.mm., leucocytes 16,200, and colour index 0.7. The differential count was: polymorphonuclear neutrophils 56 per cent., polymorphonuclear eosinophil 1 per cent., lymphocytes 41 per cent., and large mononuclear 2 per cent. Films showed nothing else of note, the condition of all the cells being normal.

The child was seen again on June 26th, when she appeared perfectly well. She had returned to school and played games with a normal amount of energy. No sign of any lung trouble. The dose of liver extract had been reduced to one teaspoonful twice daily, which she is continuing to take.

In conclusion I wish to express my thanks to Dr. C. P. Lapage, of Manchester, for his interest and advice, to Dr. Munn, of Halifax, and to the pathologists of Halifax Infirmary and St. Mary's Hospital, Manchester.

HAEMORRHAGIC NON-PUSTULAR SMALL POX

BY

ALEXANDER CANNON

LECTURER IN MORBID ANATOMY, UNIVERSITY OF HONG KONG, PHYSICIAN, COLONIAL MEDICAL SERVICE

AND

S. W. PHOON,

MEDICAL SUPERINTENDENT, TUNG WAH HOSPITAL, HONG KONG; FORMERLY CHIEF ASSISTANT TO THE PROFESSOR OF SURGERY, UNIVERSITY OF HONG KONG.

The case here reported is one of several which clinically and pathologically portray a picture of haemorrhagic non-pustular small pox occurring in the colony of Hong-Kong. It is interesting to note that most of these cases occurred in pregnant women during the eighth month of pregnancy, and hence gave us serious thought as regards revision of the diagnosis. After very careful consideration of all the facts we felt, however, that we should still stand by our provisional diagnosis.

History

The Chinese are very reluctant to give facts relating to their indisposition, and hence we are not able to supply fuller details, although we consider the history very incomplete. The patient stated that she was 22 years old and that on November 23rd, 1929, she complained of pain in the sacrum of a very severe character, she resorted to the Chinese method of thumping the affected part in an endeavour to get relief, but was not successful. Three days later there was fever, and the movements of an eight months foetus were felt, uterine pain was felt resembling that of commencing labour. The lips rapidly became cracked, and sordes developed on the mucous membrane. An aphthous condition appeared on the gums and ulcerations here and there on the tongue. Soon afterwards there were rigors and cold sweats, with nausea and vomiting, all these signs and symptoms occurred for the first time within a very short period of each other.

The patient said that her condition was due to "Lup sik" (fever after sexual intercourse), which had taken place ten days previously. The Chinese have a superstition that a woman in advanced pregnancy may die if she has sexual intercourse with her husband, and state that the condition is allied to a "severe type of pneumonia". There was no cough in spite of the rapid respiration, and there were no convincing signs of pneumonia.

Condition on Admission

On November 28th, 1929, she sought admission to the Tung Wah Hospital, stating that her eyes had become very sore on the previous day. She had suffered conjunctivitis and marked lachrymation. The face was flushed, and the body showed a nodular rash, which was not itchy. It was ascertained that the patient was a primipara and had only been married in the previous July. She had never had swelling of either the face or the feet. She was vaccinated against small pox in her native village some time ago; how long ago and whether the vaccination was carried out correctly or not, could not be ascertained, but there was no clinical evidence of vaccination ever having been performed.

Complaint was made of severe aching of the bones with great discomfort. Not once during her period of pregnancy had she ever left her bedroom. There was no evident history of syphilis. The faeces were yellow and soft in appearance, and since admission the bowels had been open three or four times daily. No blood or mucus was seen. The urine was a little concentrated and when passed was said to produce a burning sensation. No albumin was found in a catheter specimen, and the specific gravity was normal. For some time there had been weakness of the legs, but no further history or physical signs of note were obtained.

The patient died in the Tung Wah Hospital on November 29th, and was sent to the Victoria public mortuary where a post mortem examination was made by one of us on the following morning.

Post mortem Findings

The liver was markedly amyloid and much increased in size. The left kidney pelvis was full of organized blood clot. The bladder contained no urine, there was slight injection of the mucous membrane. The mesentery showed marked numerous petechial haemorrhage. The spleen was congested but otherwise normal in appearance. In the intestines, including the colon, there were many circular and irregular oval dark red or black patch haemorrhages of average size (0.5 cm.) remote from the mesenteric margin.

The uterus contained an apparently normal eight months foetus. The stomach showed large oval dark red haemorrhages on the greater curvature chiefly. There were also marked petechial haemorrhages on both the pericardium and epicardium more marked within two inches of the apex. The lungs were only congested, and the larynx and pharynx were injected with no evidence of diphtheria or other infection. On the gums there were petechial haemorrhage, no blue line, and no dental caries. The brain and meninges were injected but there was no evidence of cerebro-spinal meningitis or of any other brain or cord condition.

The breasts were well developed and contained lacteal fluid, in the fatty areolar tissue there were petechial haemorrhages. The joints showed no evidence of haemorrhage nor of any abnormality. The pupils were dilated slightly reddened and beginning to sink. The blood vessels were thickened. There was a diffuse purplish rash over the whole of the face, neck, front and part of the upper extremities but it only extended for two inches below the coracoid. It could be felt as a raised area in a traving-out of petechiae. Haemorrhages were present to the unaffected parts. A frozen section [illegible] sights was like that seen in [illegible] fever. Intestinal [illegible] and inhibitum [illegible] appendix [illegible] to other abnormality was noted.

DIFFERENTIAL DIAGNOSIS

The following alternative diagnoses were [illegible] haemorrhagic small pox (the purpuric [illegible] of Tidy) purpura haemorrhagica and [illegible] severe typhoid fever (no typhoid spleen and Peyer's patches were evident). Henoch's purpura (age limit 5 years only), lead poisoning (the macroscopic [illegible] present, but there was an appearance resembling basophilic stippling), drop-foot-drop mechanical purpura (possibly caused by rigors, as this is due to pressure of the foetus), acute leukaemia (no glands were enlarged as would be expected), chloroma (not examined, but no evidence of green marrow), cerebro-spinal meningitis (the pathology was negative), infective endocarditis with secondary septic manifestations, toxic nephritis or premonitory [illegible] conjunctivitis which required further diagnosis [illegible] since the local condition was considered [illegible] origin), and typhus fever. After a very careful consideration of all the signs and symptoms and post mortem findings, the differential diagnosis was gradually reduced to one or three conditions—namely, haemorrhagic small pox or the non-pustular variety, typhus fever, [illegible] purpura. Lead poisoning had been excluded by examination of all the organs by the Government [illegible]

chemist, Mr. E. R. Dovey, who also assured us that all other poisons were absent, so far as chemical analysis could show.

As regards the rash, those produced by quinine, belladonna, iodides, etc., were carefully eliminated. Typhus fever was not considered in view of the previously mentioned findings—bearing in mind that the rash never appears on the face in typhus, whereas in the present case there was a marked diffuse haemorrhagic rash, and noting that the spleen was not enlarged, leucocytosis was absent, and marked leucopenia was present, with general anaemia.

The total red blood corpuscles numbered about 2,000,000 per c.mm. The white cell count was constantly about. polymorphs 26 per cent., lymphocytes 73 per cent., and mast cells 1 per cent. No eosinophils were seen at any time, and no malarial parasites were detected.

The possibility of mechanical purpura of pregnancy was excluded on the grounds that there was no evidence of circulatory obstruction at all. Neither the uterus nor the foetus showed anything abnormal.

Microscopical sections were made from various parts of every organ, but all that could be noticed was simple haemorrhagic infiltration of the various organs, and nothing more.

Since one of us is now in England, and can deal with any correspondence, we shall be grateful for any criticisms and suggestions which may throw further light upon these cases.

We wish to take this opportunity of thanking the members of the University and Government staff who so kindly regularly assist us in our investigations.

THE BASIC BLOOD PRESSURE IN RAYNAUD'S DISEASE.

BY

G. ARBOUR STEPHENS, M.D.,

CONSULTING CARDIOLOGIST, KING EDWARD VII WELSH NATIONAL MEMORIAL ASSOCIATION; SENIOR CONSULTING PHYSICIAN, CARDIGAN AND DISTRICT MEMORIAL HOSPITAL.

THE basic blood pressure is that pressure exerted on the blood by the contractile walls independently of the additional pressure due to the systolic contraction of the heart. During estimations of the systolic pressure, when the inflated armlet prevents the systolic pressure from being transmitted beyond the point of application, the blood in the vessels beyond the armlet is under a basic pressure which can be estimated by my method described in the *Journal* of February 8th (p. 242).

After examining a large number of apparently healthy men I find that the normal basic blood pressure is about 50 mm. of mercury. When the second sphygmomanometer points to 70 mm. it is evident that the pressure is too high, and that the cells in the blood are being compressed to an extent which handicaps them seriously in their work. Variation of pressure on the blood disturbs the surface tension, osmotic effects, and metabolic reactions of its cells, and a permanently high figure has a serious action on the cellular actions, reactions, and interactions, with a consequently marked effect on the general nourishment of the body. Furthermore, if the pressure is very high the patency of the vasa vasorum is reduced, and the blood supply to the muscular fibres of the arterial walls is hindered to a serious extent. Under such circumstances it follows that these arterial muscular fibres are poorly nourished and their movements become sluggish. This, I suggest, is the state of things in a patient suffering from Raynaud's disease.

In cases of this disease which I have examined the systolic pressure is high, but the basal blood pressure is raised disproportionately, and I think most stress should be laid on the disproportion. In one severe case of a woman, aged 42, the systolic pressure was 200 mm. and the basal blood pressure 100 mm. This patient's nose and hands were badly affected, and her general health was so interfered with that she could not keep herself warm by the exertion involved in routine work.

My findings are increased in value as a result of the good work by Sir Thomas Lewis and Professor William Kerr, to which reference was made in the *Journal* of July 20th, 1929 (p. 111), and of January 11th, 1930 (p. 82). These observers draw attention to the fact that undue cooling of the hand failed to bring on an attack, because, as they point out, "the minute vessels of the skin of these patients react, as do those of normal skin, to excessive cold by dilating."

I venture to suggest that what really happens is this: in Raynaud's disease the basal blood pressure is high, the blood cell reactions are hampered, and there is a hindrance to the entry of this blood to the vasa vasorum, with the result that the muscle fibres are badly supplied with nourishment and are therefore not able to react satisfactorily to ordinary stimuli. Excessive cold, however, is sufficiently stimulating to make even these sluggish muscular fibres react, and, as Lewis and Kerr state, "the occurrence of a full cyanotic tint is not observed." Their observations, it is interesting to note, have made them come to the same conclusion as I have—that there is an abnormality of the vessel, and also that the closure is not reflex.

I feel inclined to differ from them when they use the term "spasm," which seems to suggest a hypercontractibility of the muscular fibres of the arterial wall. Such a hypercontractibility is not what one would expect to find in a badly nourished muscle, but rather a sluggishness of the movements. As I pointed out in the *Practitioner* of [illegible] 1929: "To suggest that the diseased muscular cells of the auricle are capable of developing fresh dysrhythmic excitation seems contrary to the usual rule of fibrillation, whereas on the other hand the diseased muscular cells forming the thin wall of the auricle lend themselves readily to a state of tremor." In Raynaud's disease the greater the heat applied within reasonable bounds, or the higher the temperature of the room, the more frequently do the arterial muscular fibres move, with a consequent dilatation, because the general raising of the temperature has helped to reduce the basal blood pressure to such an extent as to allow a freer entrance of blood into the vasa vasorum.

The connection [illegible] of a study of this sort is not so much in the milder [illegible] with Raynaud's disease itself, since, save for because it [illegible] forms, it is a rare complaint, but rather principles, [illegible] helps to emphasize one or two important supply to the [illegible] first being the importance of a proper blood secondly, the [illegible] muscular fibres of the arterial walls, and necessarily the [illegible] blood pressure taken over the arm is not body. The [illegible] pressure on the blood in all parts of the disease is evident [illegible] greater liability of the coronary arteries to their muscular [illegible] case of the fact that the blood supply of there is a [illegible] sometimes is often inadequate; as a consequence rise to many [illegible] made [illegible] ness of their movements which gives It is fairly obvious [illegible] cells [illegible] abnormal contractions of the heart. to the powerful [illegible] The [illegible] easily understandable that, owing pressure in the [illegible] 57.5 per [illegible] tractions of the heart muscle, the of all. [illegible] locytes [illegible] mary arteries must be the highest [illegible] pe of [illegible] ated [illegible] to [illegible] inves[illegible] ly t[illegible] nt [illegible] hocy [illegible] he [illegible] anis[illegible] ase

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

THE SAUERBRUCH-HERRMANNSDORFER-GERSON DIET.

THIS subject is in the forefront of medical interest and discussion in Germany at the present time, and there are many large institutions in which a special kitchen has been provided for the nutrition of patients on these lines. The work of Sauerbruch and Herrmannsdorfer extends over a period of five years; that of Gerson has been still longer. It is advisable to point out that the claims made by Sauerbruch and Herrmannsdorfer refer to the treatment primarily and mainly of surgical tuberculosis—that is of cases of lupus, and tuberculosis of the skin and bones as well as of the lungs. Stated shortly, these claims are largely the results of observations made by Herrmannsdorfer as to the influence of diet in the healing of wounds, and of the special value of the salt-free diet, and a diet

rich in vitamins supplemented by special mechanical preparations, in influencing the reactions of the tissues in a manner favourable to a normal healing process.

Gerson is of opinion that the nutritional state of the tissues—the constitution—can be profoundly influenced by a dietetic regime in which the essential points are summarized as follows: (1) the withholding of common salt in the dietary with the administration of an almost chloride-free diet; (2) a high vitamin content in the dietary, into which fresh vegetables and fruits largely enter, and (3) the administration of special mineral salts—mineralogen—prepared from the vegetable kingdom, and an additional vitamin in the form of a special phosphorized cod-liver oil preparation.

The Dietary System.

The essentials in the diet system are as follows: (1) the all but complete exclusion of sodium chloride (Heirmannsdorfer), salt being entirely excluded in the Gerson regime, and a halogen-free vegetable kitchen salt preparation—eugusal—being used as an effective substitute; (2) fresh uncooked vegetables and fruits bulk largely in the diet, either in the form of vegetable extracts prepared by pressing uncooked vegetables, such as carrots, beet, spinach, turnips, or in the form of salads, with fruit juices similarly prepared by pressing and straining, (3) marked restriction in the amount of fresh meat foods, 600 grams weekly being allowed in Heirmannsdorfer's system, while Gerson allows meat once or twice weekly; (4) one pint or more of fresh uncooked milk daily, sour milk, eggs (especially yolks), oatmeal, wholemeal bread, and farinaceous foods in restricted amounts; and (5) various spices are used to increase the flavour of the dishes. The regime also includes two medicinal preparations:[1] mineralogen, a special blend of mineral salts of vegetable origin, and a phosphoric acid cod-liver oil preparation, both being administered three times daily.

If care is taken, an entirely adequate, palatable, daily dietary can be prepared. At the conclusion of the treatment the patients get back gradually to a more conventional regime, which, however, still comprises the greater use of fresh vegetables and fruits and a judicious restriction of meat foods.

CHALMERS WATSON, M.D., F.R.C.P.Ed.,
Senior Physician, Royal Infirmary, Edinburgh.

MENINGITIS IN A BREAST-FED BABY

THE interesting feature of the case recorded below is the source of infection. The child had been entirely breast-fed, and had been perfectly well since birth. The father and mother and eight other children are all well, and apparently free from infection. The only history of tuberculosis that could be obtained was that the former occupant of the house had died of phthisis on June 29th, 1926, but as this was three years before the birth of the baby it is unlikely that it is of any significance.

John R., aged 9 months, was admitted as a case of bronchitis. Temperature was 100° F., respiration 40, and pulse 120. There were scattered moist sounds over the posterior aspect of the chest. He was pale and rather listless, but he took his feeds well and on the morning of the third day his temperature had returned to normal. It rose again that evening to 100°, and he took his feeds rather unwillingly. The next morning he was drowsy, but there were no definite symptoms; the chest had improved; the abdomen was full and soft, and not tender on palpation, there was no head retraction, and no vomiting had occurred.

On the following day he was very drowsy. Examination revealed that he had a hemiparesis of the left side; the left side of the face was immobile when he cried, and his arm and leg were flaccid. The eyes were examined, but there was no papilloedema, the discs being paler than normal. On the sixth day he had three convulsions, and a lumbar puncture was performed, 16 c.cm. of an opalescent fluid was obtained and examined by the pathologist to the hospital. He reported that the cellular content was almost entirely polymorph in character, and only a few lymphocytes were seen. Despite the unusual cell count, ten tubercle bacilli were found, all in one small group.

I would like to thank Dr. Armstrong for his permission to publish this case, and for his kind assistance.

D. M. MACK.
Liverpool Children's Hospital.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

DORSET AND WEST HANTS BRANCH.

The Problem of the Care of the Neurotic Patient.

IN a paper read at a meeting of the Dorset and West Hants Branch, on July 2nd, Dr. J. A. PRIDHAM pleaded for a more scientific and rational investigation and treatment of patients suffering from neurosis or psychosis, partly for the sake of the patient, and partly for the credit of the medical profession.

Dr. Pridham remarked that these patients wandered from doctor to doctor and to every variety of unregistered practitioner, spending fortunes on patent remedies. With each doctor they might acquire a new diagnosis and treatment; they might also be subjected to unnecessary operations and to other useless procedures, and not unnaturally they turned away in disgust from the orthodox physician. It might easily happen that some quack or some patent remedy relieved the particular trouble; this "cure" was then proclaimed abroad, and the credit of the profession suffered accordingly, the fact that new symptoms shortly appeared not affecting the position. Such patients had frequently been labelled as suffering from organic disease, and in this way certain methods of treatment, orthodox or not, had gained spurious reputations. The power of suggestion strongly affected this type of individual, and any form of treatment might produce good results if it utilized this power. The public should not be blamed for resorting to persons outside the orthodox ranks, since so many doctors would have nothing to do with a patient when once a diagnosis of neurosis had been made. In too many cases the patient realized that he was regarded as a malingerer, or despised as a poor sort of creature.

Dr. Pridham recalled that, when a student at hospital, he attended one afternoon the out-patient department of a certain physician who was justly believed to be clever and competent. An old woman came haltingly up the room, and the students were asked to observe her peculiar crippling gait, which the physician pointed out was not characteristic of any known disease, and was in fact hysterical. The patient was dismissed, and we were left with the impression that she was not a sick person needing relief, but someone to be laughed at and anyway quite outside the scope of medicine. Yet this old woman had travelled hopefully to the hospital, expecting to be cured of what was to her a serious disability. The speaker expressed the view that this unreasonable attitude of mind was the result of the reaction of medicine from the centuries of ignorance and of the blind acceptance of unsound theories. With the renaissance of science, theories had to be based on observations of fact. The scientific physician learned that he must found his study of disease on the facts of anatomy, physiology, and pathology. He was far too occupied with these studies to be able or willing to be interested in maladies that revealed no trace of organic origin; in fact, he did not regard them as maladies at all, but rather as a peculiar form of amusement of the patient. This opinion was often only slightly veiled, and it was hardly surprising that the patient thought little of the orthodox healer. This mental attitude still persisted among a large number of doctors. Another source of error was the battle which still raged between the somatists or mechanists and the psychologists. The former maintained that all disorders, including the neuroses, were due to organic disease, known or unknown. It could be admitted that a sound mind was unlikely to exist in an imperfect body, for the imperfection of the body might prevent the normal development of the mind, or it might prevent the mind from functioning naturally. But the opposite argument also held good—namely, that a diseased mind might harm a sound body. A ship might be commanded by a capable captain, but if it was badly constructed the most capable captain might be unable to prevent disaster; on the other hand, a good ship commanded by a fool might go on the rocks.

Reviews.

FAITH AND SCIENCE IN SURGERY.

LAST May, when congratulating Sir JOHN BLAND-SUTTON on his seventy-fifth birthday, we expressed a hope that we might have further proofs of his ability to charm us. One such proof has lately come to hand in a reprint of ten addresses, *On Faith and Science in Surgery*,[1] delivered in the lustrum 1925-30 in various cities of Great Britain and Canada, re-edited and freely illustrated with wood engravings. Some part of these have already appeared in our pages with some of the woodcuts which adorn them, but they are none the less welcome in their present form. Sir John has not only the faculty of presenting new facts attractively: he has the power of seeing long-known facts from new points of view, and of shaking the reader's complacency by reminding him of gaps in his knowledge and of defects in his surgical equipment. Like Mr. Silas Wegg (in this respect alone), he has a habit of "dropping into poetry" and of driving home some of his arguments and aphorisms with rhymes, such as those in the Mitchell Banks Lecture of 1925. He is by no means satisfied with catgut for sutures or ligatures, for he lays it down as an axiom that "no material should be employed that cannot be sterilized by heat without destroying its efficiency," and also, "surgeons still require a reliable ligature." Perhaps the procedure of Gallie, commended by Sir John Bland-Sutton, may satisfy the counsels of perfection by employing strips of the patient's own fascia as ligature and suture materials. The surgeon might at any rate have the satisfaction in such cases of throwing the blame on the patient for any failures of material.

"To operate for acute cholecystitis and not remove the gall-bladder is as reprehensible as operating for gangrenous appendicitis and leaving the appendix." Thus does the author sum up his lecture on faith in drugs, in which he prescribes "Attic salt for gall-stones." Yet how shall we expect the layman to realize the facts when, as Sir John relates: "In 1894 a medical student submitted to cholecystotomy for calculus obstruction: the fistula has been discharging mucus and bile to the present time—thirty years. This man clings obstinately to his gall-bladder, and has used more than a ton of cotton-wool for absorbing the escaping bile." The article on conjoined twins and monstrosity and its illustrations are attractive, and that on the parasitic origin of man is most instructive and impressive from its clear simplicity of statement of profound truths. The addenda remind us of the author's pioneer work on avian tuberculosis, and to some ancient instances of couching for cataract. We must not conclude without commending the illustrations. In these days clear woodcuts are most refreshing, and in particular such illustrations as those of the wonderful nest of a tailor-bird or the quadruplets from an armadillo.

There is much virtue in these one hundred and nine pages.

LECTURES ON BIOLOGICAL MEDICINE.

As representing the medical revival in Italy nothing could be more appropriate than the volume of Lectures on Biological Medicine,[2] edited by Professor MARTELLI of Naples. Professor Martelli is the editor of the "Medical Renaissance," and the present volume contains a number of carefully chosen articles by various distinguished representatives of Italian medicine which have appeared in that periodical during the last few years. The result is a volume bearing some resemblance to the well-known work of Trousseau, with the addition of certain artistic features which mark its Italian origin. Most of the articles deal with familiar subjects, such as appendicitis and typhoid fever, and need not be enumerated; but Professor Martelli has contributed an original article on the new horizon in medical biology, which is of particular interest at the present time. He pictures the various stages which modern medical science has traversed, beginning with the anatomical period initiated by Morgagni, culminating in the cellular pathology of Virchow. This stage passed away when it was realized that the study of the corpse alone, although indispensable, failed to give an explanation of the genesis of disease—an essential to successful treatment. The discoveries of Pasteur, with their revelation of the *immense world of the infinitely little*, ushered in the etiological period. So great at the time was the enthusiasm aroused by bacteriological research, that the body itself tended to drop out of view, but when the enthusiasm declined somewhat it was discovered that these parasites alone offered no sufficient explanation of disease—that they might be present without causing disease, and that in epidemics not every exposed individual became infected. The existence of a definite receptivity or constitution was recognized, "our Giovanni" being a pioneer in the movement. Thus was introduced the modern pathogenic period with its elaborate technique. The point of Professor Martelli's argument is that a further stage has to be reached before the final aim of medicine—namely, that of prophylaxis, can be attained. Present knowledge and clinical acumen too often end merely in the contemplation of the results of disease. Such conditions as pulmonary cavitation, hepatic cirrhosis, and sclerosis of the spinal cord, for example, are not, he contends, diseases, but the results of disease and evidences of the failure of the body in its contest with pathogenic agents. It is futile merely to contemplate, like Marius among the ruins, the havoc produced on the body. The author perceives an early stage of variable duration in different diseases, during which the healthy organism is struggling against the settlement of the pathogenic agent within it. It is to this pre-pathogenic stage, that research should be directed as affording the best hope of discovering the means of successful prophylaxis. He has himself studied the signs and symptoms of this stage in connexion with certain diseases, and he has endeavoured, in his teaching, to demonstrate that, in the case of leukaemia, for example, it is quite possible to recognize them. He recommends investigators to concentrate their attention on what Héricourt has called these "frontiers of disease."

under discussion. Above all, he lays stress on the important fact that, given patience and care on the part of the physician, and much fortitude on the part of the patient, really good results may be obtained.

MENTAL HYGIENE.

Foundations of Mental Health[1] is a translation of the last published book of the late Professor LEONARDO BIANCHI. The author was not only a psychiatrist of the highest eminence, but also a statesman, who, as Minister of Public Instruction in Italy, was entrusted with the direction of the educational affairs of his country, and continued up to the end of his life to exert a profound influence in matters concerning the health and welfare of the community. The last work of this eminent clinician and scientist on what is perhaps one of the most important medical and social problems of the present day—namely, the mental health of the race—will naturally be read with interest by English-speaking readers; for while, as Dr. Francis X. Dercum observes in an introductory note, this book is written from experience based upon a study of Italian people, the problems considered are those which are presented by all other races and nations. In successive chapters Professor Bianchi discusses the conditions in which human beings are generated, including the laws regulating heredity; the conditions in which infancy is developed, with special regard to weak constitutions and anomalies of character; the school period; the value of physical, moral, and sex education; criminality and its causes; the general unfavourable conditions in which national groups are living; habits threatening health, as alcoholism; the conditions favouring diffusion of diseases disastrous to individuals and to family life, as syphilis; and the causes of the enormous increase of mental diseases and their remedial measures. This book is written with vigour and courage, and Professor Bianchi does not shrink from denouncing errors or weakness in the Church, in the educational system, or in the habits of the people. In the sphere of morals he counsels restraint and self-denial, and in that of religion the necessity for the educationist to explain the perfect agreement between the moral content of the Christian religion and the naturalistic interpretation of the universe.

TAYLOR AND POULTON'S "MEDICINE."

THIS well-known *Practice of Medicine*[5] is now in its fortieth year, for in 1890, four years after the appearance of the much larger *Principles and Practice* of Hilton Fagge, the late Sir Frederick Taylor brought out the first edition of a book which by the piety of his successors still perpetuates his name, and by its size and detail contrasts with the conjoint *Textbook of Medicine* (1929), edited by Dr. J. J. Conybeare, yet another member of the great school of Guy's Hospital. Since the thirteenth edition in 1925 Dr. POULTON has made many changes and additions, but by judicious pruning of the text has kept the volume of practically the same size. The difficulty that one man must feel in covering the whole ground of medicine is ever increasing, and in this edition Dr. R. D. Gillespie becomes responsible for a new section on mental diseases, and Dr. Dyce Sharp has revised and largely rewritten that on tropical diseases, in which those due to parasitic worms are now included. There is a new article on chronic gastritis, in which the view is taken that in the absence of severe anaemia or of gastric carcinoma a persistent achlorhydria points to chronic gastritis. A great deal of new knowledge has of course been incorporated—for example, the liver treatment of Addisonian or glossitic anaemia, J. W. McNee's classification of the forms of splenic enlargement associated with anaemia, and in Dr. H. W. Barber's account of cutaneous diseases. A noticeable feature of the volume is the number of excellent radiograms, and it is a matter for pleasant surprise that the cost of this valuable book has been actually reduced since the last edition. The amount of work devoted to this edition, even allowing for the editor's generous acknowledgments of help from others, must have been enormous, and the result is certainly most successful.

NURSERY MANAGEMENT.

PROFESSOR MARION L. FAEGRE and JOHN E. ANDERSON, director of the Institute of Child Welfare, University of Minnesota, have collaborated to produce an interesting little book on *Child Care and Training*.[6] Attention of late years has been much directed to the care of the pre-school child, and more and more emphasis is laid on the results of early training, not only in the adaptation to life of individual children, but in the development in all children of what is often called "character." That character is less the outcome of heredity than of environment is one of the points stressed in this book, and parents are repeatedly urged to provide the atmosphere which will develop the most useful tendencies in their children. This is not an easy matter for most adults, who may find themselves humbly lacking in the serene and omniscient qualities that appear to be essential for the perfect parent. But the authors of this book are at pains to describe possible errors and to offer examples of suitable modifications of behaviour of the parents. The early acquisition of good habits in eating and sleeping, coupled with a bond of trust between children and parents, makes a good basis for later management. Chapters on play and books and reading are written with great insight into the point of view of the child, and there is an interesting discussion of the development and proper guidance of curiosity. The book as a whole embodies a review of modern ideas on child guidance.

In *The New-born Infant*[7] Dr. EMERSON L. STONE offers an amplification of a series of lectures given to fourth-year medical students. As he justly points out, there is a gap in the supervision of the newly born child between the time when the obstetrician loses sight of the case and the time when the infant is first taken to a paediatrician or a welfare clinic; yet in the first few weeks of life bad habits may be formed, and serious digestive or other disturbances may arise, which might be avoided by careful management from the outset. Such management he outlines in the book, discussing diverse views held on many points of treatment, and indicating his own preference in each case. The first chapter deals with the immediate care of the newly born child, including the treatment of asphyxia; Dr. Stone, while deprecating the use of violent forms of artificial respiration, approves mouth-to-mouth breathing and the use of hot and cold baths. Passing on to the nursing of the normal infant the author gives useful advice on the care of the child and the establishment of regular habits in feeding, sleep, and excretion. A chapter on dietary disorders of infancy, grouped under symptomatic headings, is well arranged and contains valuable information briefly set forth. The remainder of the book is devoted to birth injuries, disorders and diseases of infancy, and the management of the premature child. The arrangement throughout is clear and concise, and the book should be useful to those who are concerned with the early care of children.

Modern Babies and Nurseries,[8] by Mrs. LEN CHALONER, is intended primarily for the use of the mother. It gives in a clear and attractive manner much practical advice on the management of children both in infancy and early

childhood. There is much sound information, based on experience, in the chapters on nursery furnishing and labour-saving devices, and in a later chapter some suggestions on a subject rarely treated—the conduct of a seaside holiday. The book is conveniently small and attractively written.

THE ACTION OF MUSCLES.

THE first edition of Sir COLIN MACKENZIE'S small volume on *The Action of Muscles*[9] was reviewed in our pages twelve years ago. The initials "A. K." at the end of the notice testified at once to the importance of the book and to the value of the opinions expressed by the reviewer. Sir Colin Mackenzie took up the work which was interrupted by the early death of Charles Beevor, whose Croonian Lectures, delivered at the Royal College of Physicians, revealed a wealth of observation and of acute deduction therefrom. The new edition now under notice differs little from the old, the principal addition being a special section dealing with the erect posture. But to the practitioner the value of this book depends mainly upon the chapters upon re-education and that coaxing of paralysed muscles to resume their functions with which Sir Colin Mackenzie made such an impression in the military orthopaedic hospitals during and soon after the war. We have no doubt whatever that this second edition will be as quickly sold out as was the first one.

NOTES ON BOOKS.

The Clinical Pathology of Thoracic Puncture Fluids,[10] by Dr. S. ROODHOUSE GLOYNE, is a book that should prove of value to laboratory workers who have no special knowledge of chest conditions. After describing the anatomy and physiology of the pleura, including an account of the lymphatic vessels, the author discusses the pathogenesis of pleural effusions, paying particular attention to the development and location of adhesions. The technique of exploratory puncture is next considered, and this is followed by a straightforward description of the simple physical, chemical, cytological, and bacteriological methods of examining the fluid withdrawn, together with an interpretation of the findings. Considering the small size of the book the cost is perhaps rather high; this is, no doubt, to be ascribed to the inclusion of a coloured plate and a number of photomicrographs, which incidentally add but little to the clarity of the text. A future edition might well include one or more differential tables giving the main properties of those fluids that are most commonly encountered.

We have received the fifth volume[11] (Herzkrankheiten II-Krebsforschung) of the new German Dictionary of Practical Medicine, edited by Professors GEORG and FELIX KLEMPERER, of which the preceding volume was published earlier in the year (see *Journal*, February 15th, p. 291). The twenty-eight articles, all by well-known authorities, are as follows: diseases of the myocardium and cardiac nerves (continued), by Professor W. H. Veil of Jena; hay fever, by Dr. H. Petow of Berlin; Hirschsprung's disease, by Professor R. Mühsam and Dr. E. Mühsam of Berlin; diseases of the testis and hydrocele, by Professor B. O. Pribram of Berlin; mountain sickness and aviators' sickness, by Professor A. Loewy of Davos; homoeopathy, by Professor Georg Klemperer; hydrocephalus, by Professor R. Henneberg of Berlin; hydrotherapy, by Dr. Georg Hanffe of Wilmersdorf; hypnosis, by Professor J. H. Schultz of Berlin; diseases of the hypophysis, by Professor C. Hegler of Hamburg; hysteria, neurasthenia, and neurosis, by Professor K. Hansen of Heidelberg; icterus, by Professor H. Eppinger of Freiburg; impotence, by Professor P. Furbringer of Berlin; infection and immunity, by Professor H. Hetsch of Frankfort; influenza, by Professor N. Ortner of Vienna; inhalation treatment, by Professor Seyderhelm of Frankfort; whooping-cough, by Professor W. Birk of Tübingen; the feeding of children, by Professor A. Schlossmann and Professor A. Eckstein of Düsseldorf; Little's disease, by Dr. E. Haase of Berlin; poliomyelitis, by Professor J. Zappert of Vienna; tuberculosis in children by Professor St. Engel of Dortmund; climate and climatotherapy, by Dr. M. van Oordt of Sonnenhof; deformities of the knee and hip-joint, by Dr. O. Stracker of Vienna; constitution, by Professor T. Brugsch of Halle; headache, by Professor F. Hartmann and Dr. E. Hofmann of Graz; cosmetics, by Dr. A. Joseph of Berlin; spasms, by Professor P. Schuster and Dr. H. Pineas of Berlin; and investigation of cancer, by Professor F. Blumenthal of Berlin.

The student of bacteriology as a pure science will find his subject admirably set out in Morrey's *Fundamentals of Bacteriology*.[12] The medical reader will not fail to find much in it that is of great interest, but he may be struck by the apparent neglect of things medical. For the bias of the book (as befits the word fundamental) tends rather towards the general than to the particular, and although the physics and chemistry of bacterial life is surveyed very ably, it may be suggested that for teaching purposes the appreciation of the general principles described might be more keenly appreciated if particular instances were adduced more fully. As a theoretical account of the subject the manual has much to recommend it, but it is for the student who has already made some practical acquaintance with bacteria. The preparation of media, the standardization of their reaction, and the technique of sterilization are of course dealt with fully, and from the laboratory point of view. Perhaps a strict adhesion to the title brings it about that there is no systematic account of such organisms as the *C. diphtheriae* or the *Eberthella* group, and the essence of serological reactions is given less from the practical than from the theoretical standpoint. The history of bacteriology is interestingly sketched, and the large part played in its growth by the study of pathogenic organisms is given its due place. The didactic attitude of the volume is reflected by the superabundance of italics and inverted commas, whose frequency is apt to destroy their object. Illustrations and indexing are good. For the student of general bacteriology the book is certainly well suited.

Among the papers included in the *Transactions of the Medico-Legal Society*[13] for the session 1928-29 is an account of the causes and symptoms of status lymphaticus by Dr. Godfrey Carter; an acute analysis by Dr. F. J. McCann of the duties of the doctor to patients mortally endangered by criminal abortion; and a sympathetic study of juvenile delinquency by Dr. Weatherly, who emphasized the importance of first determining the cause of antisocial behaviour. The most closely argued debate was evidently that in which Lord Riddell and Dr. McCann as protagonists discussed the subject of the sterilization of the unfit; and opinion was sharply divided on most points. Other papers—none of them without some incisive quality—dealt with fume diseases, firearm injuries, and acute arsenical poisoning. Dr. Temple Grey gave an instructive account of the medico-legal expert in France.

The thirty-eighth edition of *The Annual Charities Register and Digest*[14] shows the care and assiduity in compilation which has distinguished the previous editions of this established work of reference. As a practical handbook for social students, and as a convenient, though comprehensive, guide for those who are interested in philanthropic activities, it continues to provide in a handy classification much concise and illuminating information of the means by which distress in affliction and sickness is relieved—in hospitals, homes, and special institutions. An elaborate appendix deals with benevolent institutions, friendly societies, and trade societies, and contains a miscellaneous section in which details are given which may be of general use to hospital almoners.

PREPARATIONS AND APPLIANCES.

METALIX-PORTABLE X-RAY TUBES.

DURING the last three years we have frequently mentioned the "metalix-portable" x-ray apparatus, manufactured by Philips Lamps Limited (145, Charing Cross Road, W.C.2), which aroused considerable interest at the trade exhibition held in connexion with the British Medical Association's Annual Meeting at Cardiff in 1928. A catalogue describing these tubes and their accessories has just reached us. It gives details of the complete range of the tubes, and furnishes a good deal of information, especially by means of photographs, as to their use from the point of view of the general practitioner. The apparatus is made ready for transport in two packages: one consists of the transformer weighing 40 lb., and the other, containing the tube itself, the time switch, and other accessories, weighs 30 lb. The whole installation can be easily taken to the patient's house and safely operated from the domestic electrical supply. The brochure is exceptionally well produced.

Nova et Vetera.

LIVES OF ENGLISH SURGEONS.

The Thelwall Thomas Memorial Volumes.

The revisers of *Plarr's Lives of the Fellows of the Royal College of Surgeons of England*,[1] which work was begun by the late librarian of the College as long ago as 1912, tell us in their preface to the two handsome volumes now published of the history of the undertaking so happily brought to fruition. Mr. Victor G. Plarr for some years diligently collected obituary notices, but his collection was found by Sir D'Arcy Power and Mr. W. G. Spencer in 1923 to be too diffuse and not sufficiently well arranged for immediate publication. It was therefore put aside temporarily, though Mr. Plarr continued to add to it. Since his death in January, 1929, the work of editing and adding to the biographies has been carried on by Sir D'Arcy Power, Mr. W. G. Spencer, and Professor G. E. Gask, who have brought it up to the date of the end of 1929, if not later.

The cost of these volumes has been defrayed out of a bequest made to the College by the late Mr. Thelwall Thomas of Liverpool, who died in 1927, and the book is accordingly entitled "The Thelwall Thomas Memorial."

A considerable number of the deceased Fellows have been personally known to the revisers, who have therefore been in a position to add characteristic details from their own knowledge. A memoir of Mr. Plarr follows the preface, after which comes a transcript of the charter of 1843, and a list of the 300 Fellows chosen from the surgeons of the day in London and the provinces, and elected *en bloc* on December 11th, 1843. In August, 1844, 240 more Fellows were elected in the same way, including twenty-nine chosen from the service of the Honourable East India Company.

These "Lives" include some 2,600 Fellows, and form a chronicle and brief abstract of the time as far as English surgery is concerned, for they include, besides the 300 (of whom one at least accepted the honour under protest, as disapproving of the innovation), Fellows by examination, Honorary Fellows, for the most part foreign, and those who, from their services to the art, have been thought worthy of election to the Fellowship after holding the diploma of Membership for a number of years (at present twenty). There have also been a very few who have been elected *ad eundum*, as possessing the diploma of Fellowship of Ireland or Edinburgh. These Fellowships have only been granted in very special circumstances.

Sir D'Arcy Power's experience as a contributor to the *Dictionary of National Biography* has doubtless stood him and his colleagues in good stead in deciding what to admit and what to omit, and he has, wisely as we think, decided in favour of accepting anecdotes and statements which throw a light on character, and at the same time prevent this vast mass of data from being dry and dull. Unfortunately, it is unavoidable that a large number of the persons discussed were not known to any of the editors, either personally or by hearsay, and the records of their careers have the formal character of too many obituary notices. The result is that there is a certain inequality of treatment. For instance, Sir Richard Owen, great comparative anatomist as he was, was notoriously grudging in acknowledgement of other men's work, and apt to claim credit which was due to others. In the notice of Sir James Paget it is stated that Owen examined his preparation of *Trichina spiralis*, determined the nature of the worm, named it, and took the credit. But in the article on Owen there is no hint at this weakness of character. Some of the anecdotes of distinguished Fellows are well known to the elders of to-day, and may perhaps by some be thought trite, but it is right that they should be put on record as some evidence of what were the personalities of the Victorian, Edwardian, and early Fifth-Georgian surgeons. For the eighty-six years since 1843 have seen great changes and enormous improvements, and even in the lifetime of the revisers there have been surgical revolutions. Even for them it must be hard to realize that they knew the day when Sydney Jones of St. Thomas's was reckoned the best operator in London, and when surgeons would travel long distances to see him do lateral lithotomy, Syme's amputation, or excision of the upper jaw, which operations were then held to be the highest tests of skill. Not one of these would divert attention from the morning paper to-day.

As might be expected, the length of the notices varies widely. Some are two lines long, and all lengths are to be found between that minimum and the seven and a half pages devoted to Sir Victor Horsley. The notice of Sir Frederick Treves is an epitome of the history of the surgical treatment of intestinal obstruction and appendicitis. It leaves us with the impression that Treves was a greater artist with the pen than with the scalpel.

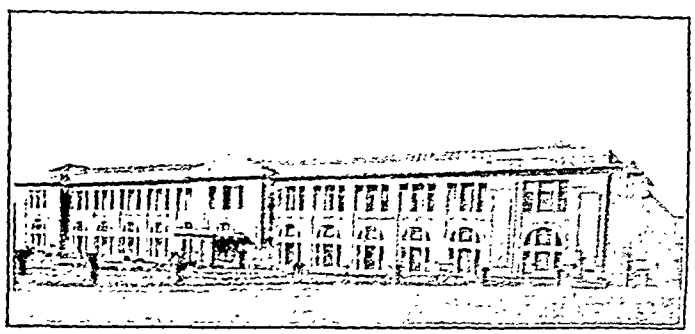
We have looked at every one of these 1,348 pages without finding a record of any Fellow being convicted of crime, although a former President of the College is credited with the "abduction" of the lady who became his wife. Unfortunately, the stress of professional worries proved too much for some, and the list of suicides is a heavy one. But, on the whole, the Fellows seem to have lasted well. We have gained the impression that an unusual proportion passed the Psalmist's maximum of life. They went and came to and from all parts of the earth, and the Roll of Honour of Fellows who gave their lives as medical missionaries is a brilliant if short one. Others devoted themselves almost wholly to science. Such were George Newport, Kitchen Parker (who "was once known to speak for four hours continuously on the lower jawbone of the raven, without saying anything that was other than valuable"), George Bennett of Sydney (the notice of whom extends to two pages), Caleb Burrell Rose, Swan, Symington, Thane, etc.

Among those who followed a military career are John Wylie of the Indian service (elected in 1844), who in the fight of Corygaum, near Poonah, in 1817, distinguished himself by attending to the wounded when he could spare time from leading the sepoys to the attack. The account of this affair in the "Lives" occupies two pages of small print, none of which could be spared. Wylie afterwards was among the first lot of medical officers to receive the C.B. This entry is a good specimen of the scale on which this work has been carried out. Space has not been grudged for the insertion of any matter of interest. John Haddy James, one of the original 300, was the subject of a regimental order of the 1st Life Guards which must surely be unique. It was dated on the day of Waterloo, and ran as follows: "Assistant Surgeon James is not in future to expose himself under fire," as it appears that he had done previously. Another distinguished army surgeon was George James Guthrie, who, at the age of 16, after due examination, was posted to the 28th Regiment as hospital mate—his colonel was 24. It was in Guthrie's quarrel in later years that another Fellow—the pugnacious Frederick J. H. Hale Thomson—fought a duel with Sir Charles Forbes on Clapham Common, as recorded, with much more interesting matter, under Thomson's name. Thomson terminated his stormy career by taking an overdose of chlorodyne.

In selecting the first 300 Fellows the claims of general practitioners were not overlooked, if we may take Thomas Callaway of the Borough High Street as an example. We are told that his practice was more medical than surgical, and a large yellow chariot and footmen seem to have played an important part in it. His son was a Fellow by examination who gained the Jacksonian Prize for an essay on dislocations and fractures of the clavicle and shoulder-joint in 1846.

We think it will be evident from what we have said that the high expectations formed on account of the repute of the author and revisers of these volumes have been amply fulfilled. The feast offered is a rich one, and we have only picked out a few of the numerous plums. A cynic has altered the old adage to "De mortuis nil nisi *bunkum*," and "debunking" the dead has become a favourite pastime among rising young writers. Such has

[1] *Plarr's Lives of the Fellows of the Royal College of Surgeons of England.* The Thelwall Thomas Memorial. Vols. i and ii. Revised by Sir D'Arcy Power, K.B.E. (Mil.), F.R.C.S.Eng., with the assistance of W. G. Spencer, O.B.E., M.S., F.R.C.S.Eng., and Professor G. E. Gask, C.M.G., D.S.O., F.R.C.S.Eng. Bristol: J. Wright and Sons, Ltd.; London: Simpkin Marshall, Ltd. 1930. (6½ × 10½, vol. i, pp. xxvi + 752; vol. ii, pp. 596. Cloth, 42s. net; half bound, 57s. 6d. net.)



not been a guiding principle of Sir D'Arcy Power and his coadjutors. Rather have they thoroughly acted up to the spirit of the lines by Dr. Johnson, quoted on the fly-leaf facing the first "Life":

"To calumniate the Dead is Baseness:
To flatter them is surely folly."

In a work of this vast scope there must, of course, be mistakes. It is intended to issue a supplement in ten years' time, which will include a list of errata and corrigenda.

MEDICAL EDUCATION IN BURMA.

In Rangoon, the capital of Burma, there is nearing completion one of the most comprehensive university building schemes in the Empire. Burma is situated on the eastern side of the Bay of Bengal, and is peopled by races of Mongolian descent, allied to the Chinese and Siamese, who are their nearest neighbours. It has been attached to India for administrative and fiscal purposes since its conquest during last century, but it has nothing in common with that country in language, customs, religion, or descent. The conception of a great residential university for Burma was due to Sir S. Harcourt Butler, who served two terms as Governor. He acquired for the purpose four hundred acres of land five miles out of Rangoon, on the banks of the Victoria Lake, one of the healthiest and most beautiful spots in the neighbourhood, and the sum of nearly one million pounds was placed by the Burma Government at the disposal of the University Building Trust for building and equipping the new university. Numerous private donors have given valuable financial assistance, the civil and mining engineering buildings having been presented by the Burma Oil Co., Ltd., at a cost of £100,000, and the students' union, boat club, university library, theatre, and gymnasium have been given entirely by private well-wishers.

COLLEGE OF MEDICINE, RANGOON UNIVERSITY.

With the exception of the medical college building, which has been erected in close proximity to the General Hospital, the whole university is being constructed on this estate, the organization of which has grown to such an extent that the question of forming a university municipality, separate from that of Rangoon, is being considered. The university is entirely residential, and is organized as two constituent colleges, University College and Judson College, the second being largely supported by mission funds from America, and the teaching staff being chiefly American. From University College, the larger institution, it is expected that the medical department will separate off as a third constituent college of the university within the next few months, as a matter of administrative convenience. The arts and science buildings are situated on either side of the main university avenue, University College being on the east side and Judson on the west. At the head of the main avenue stands the convocation building, the chief architectural feature of the estate. In its main hall there is seating accommodation for over two thousand persons, and this building also contains the council and senate chambers and the university offices. The undergraduates are comfortably housed in nine three-story halls, each accommodating a hundred and twenty students in separate rooms, with quarters for a number of assistant wardens and tutors. There are also houses for wardens and for most of the full-time members of the staff. Modern sanitation and plumbing, with supplies of hot and cold water, are provided in all buildings, and electric light and power and modern cooking ranges are universally available. Ample playing grounds have been laid out for all forms of games; the university rowing club is in a specially flourishing condition, and the military training corps has a large membership.

At the beginning of the present century Rangoon was very backward so far as her public buildings were concerned, the hospitals and schools, especially, being out of date. Since then conditions have changed with almost bewildering rapidity. The result is that the General Hospital (550 beds), the newly constructed Dufferin Hospital for Women, and the Mental Hospital are of the most modern type, well planned and splendidly equipped. There are, therefore, in Rangoon, with its 400,000 inhabitants, all the clinical facilities for medical education of university standard, and in 1923 the first batch of M.B. students, having passed the university intermediate examination, entered on the newly instituted courses in temporary buildings. The M.B., B.S. degrees of the University of Rangoon were conferred for the first time in July, 1929, on ten recipients, nearly all of whom at once enrolled as members of the British Medical Association. After matriculation, students in Burma must spend a minimum of seven years at the university in order to obtain the M.B., B.S. degrees. The first two years are occupied in intermediate work in arts and science for the university intermediate examination, the remaining five being spent as in England—two years preclinical and three years clinical.

The new medical college building was opened in October, 1929, and in design and equipment is unsurpassed by any medical teaching institute in Asia. It takes the form of a square two-story building, with a frontage of 300 feet; it is arranged round a quadrangle, into which the two superimposed main lecture theatres project. The ground floor accommodates the departments of physiology (including histology and biochemistry) and forensic medicine, three lecture theatres, the examination hall, offices, cloak rooms, lavatories, and students' common rooms. On the second floor are the departments of anatomy, [illegible] surgery, pharmacology and materia medica, pathology and bacteriology, the library, a large lecture theatre, and several small seminar rooms. Animal rooms and gas plant are situated in separate buildings at the rear of the [illegible] structure. Hygiene is taught in the [illegible] Institute of Public Health, the director of which [illegible] the university lecturer in hygiene. University [illegible] provided clinical and post-mortem [illegible] modern type at the hospitals. Apart from [illegible] completeness of equipment and the [illegible] anatomical material, the points which [illegible] experienced visitor are the splendidly arranged [illegible] stocked museums in the pathology and forensic [illegible] departments. This is due, not only to the keenness of the staffs concerned, but to the facts that there are over one thousand complete necropsies performed annually in the Rangoon General Hospital and that crime with violence is notoriously prevalent.

There are seven university medical chairs—anatomy, physiology, pathology, forensic medicine, surgery, medicine, and obstetrics. The heads of the remaining departments have the status of university lecturers. All the heads of departments of medical teaching are European, as is, practically speaking, the case in the arts, science, engineering, and law departments also. The dean of medical studies is Lieutenant-Colonel T. F. Owen, I.M.S., professor of forensic medicine. In conjunction with the consulting architect, Mr. S. P. Bush, A.R.I.B.A., he has played the leading part in designing and equipping the college of medicine

British Medical Journal.

SATURDAY, AUGUST 23RD, 1930.

A CENTURY OF HEALTH PROGRESS IN GLASGOW.

If at the first the great cities of this country fostered the evils which conduce to disease prevalence and mortality, they have in most cases in the course of years succeeded in discovering and working out appropriate and effective remedies. During the earlier part of the nineteenth century, when the local massing of the industrial population ensured the rapid spread of any communicable disease from its point of origin, the city of Glasgow was repeatedly swept by the major infections. The frequency of those outbreaks then forms a striking contrast to the comparative immunity which the city now enjoys, despite the fact that its population has not only become more industrialized than ever but has also increased to a notable degree in its total number. This change for the better, while doubtless attributable in part to causes of a general nature, is due also in substantial measure to the competence and ability of the medical administrators to whom the health affairs of the city were entrusted. Its first medical officer was Sir William Gairdner, its second was Dr. J. B. Russell, and its third was Dr. A. K. Chalmers. Though now retired from office, Dr. Chalmers has not abandoned the life-long habit of public service, but has devoted the beginning of his leisure to the preparation of a review of the sanitary progress of the city. In *The Health of Glasgow, 1818-1925*,[1] he has traced the course of the movement in the city which sought to adapt the new industrial conditions to the requirements of healthy living so as to produce a race which, though industrialized, should yet be fully vigorous.

As the history of sanitary reform in Glasgow has been to a large extent the history of reform in its housing conditions, Dr. Chalmers opens with an account of the improvement in housing standards. He recognizes that every form of shelter which man has devised to protect himself from the elements limits to some degree the free play around him of forces essential to his well-being, especially fresh air and sunlight. The fever of 1818 had directed attention to the prevailing squalor of the affected districts, yet the wynds and closes of Glasgow in 1849, a year of epidemic cholera, were still such as to be described by contemporary writers as "frightful abodes of human misery." The rapid growth of the city accentuated the grosser defects of the tenement system of housing and increased the difficulty of applying remedies on the large scale. A provisional datum of habitability was first laid down in a local Act of 1862. Succeeding Acts from 1886 to 1900 progressively increased the stringency of requirements till the general Housing Act of 1919 ushered in the era of State-aided housing schemes. The improvement of housing standards as reflected in the increased number of apartments in new houses is well brought out in a table which covers the period from 1872 to 1926. In 1872-73, of 4,463 new houses authorized 1,338 were of one apartment, 2,198 of two apartments, 802 of three apartments, and the rest of four apartments and over. In 1925-26, of 6,796 new houses authorized none were of one apartment, and only 318 were of two apartments, while 4,649 were of three apartments, and the rest of four apartments and over.

In the campaign against tuberculosis the Corporation of Glasgow was early in the field. In 1889, within five years of Koch's discovery of the bacillus, it obtained a decision in court upholding its condemnation of a tuberculous carcase, and in 1890 its amending Police Act contained provisions for dealing with tuberculous meat and milk. An inquiry made in Glasgow in 1897 revealed a correspondence between a high number of persons per room in houses and a high phthisis death rate. In 1899 a public health laboratory was opened for the examination of sputum and other discharges. In 1900 notifications of phthisis began to be received from general and Poor Law hospitals and dispensaries, and in 1903 a medical assistant was appointed to follow up phthisis cases. In 1906 the first dispensary for consumptives was opened, and four years later pulmonary tuberculosis became generally notifiable in Glasgow. The National Insurance Act of 1911 and the Treasury grant which it empowered led to a wide extension of institutional accommodation for tuberculosis, which culminated in Mearnskirk Sanatorium.

An early step for the control of infant mortality was the inauguration in 1904 of the depot at Osborne Street for the preparation of milk for infants. Consultations for infants were begun in 1906 with a nucleus of the babies supplied by the depot, and classes were set on foot for the education of mothers in infant hygiene. In 1906, also, the first woman medical officer was appointed. In 1907 the Notification of Births Act brought the occurrence of births under the notice of officials within thirty-six hours. When the Osborne Street Depot, having served its purpose, was closed in 1909, official health visitors were added to the public health staff. The provision for the treatment of expectant and nursing mothers and pre-school children empowered by the Notification of Births (Extension) Act of 1915, although welcomed by Dr. Chalmers, was regarded by him as essentially auxiliary so far as Glasgow was concerned, inasmuch as it could only produce the best results if associated with reform in the housing conditions of the city on a wider scale than had up till then been attempted. Nevertheless, he utilized the facilities of the Act to their full extent, devising schemes for the basic services with extensive primary and secondary developments in every field of maternity and child welfare work. He notes that the operation in Glasgow of the Midwives (Scotland) Act, 1915, was followed by a rise in the number of notifications of puerperal fever—not, he considers, because of any increased frequency in the occurrence of cases, but because of the resulting keener scrutiny of the causes of febrile states in parturient women. He emphasizes the unsatisfactory nature of the home treatment of ophthalmia neonatorum, as a result of which provision was made for the admission of infants affected, and their mothers, to Baird Street Reception House.

Cholera was among the first of the major infections to feel the curb of sanitary reform. During the third pandemic in 1854 there were 3,886 deaths from cholera in Glasgow: during the fourth, in 1866, after the introduction of Loch Katrine water, only 68. Typhus yielded in its turn; in 1847 it caused 4,346 deaths, and it is now approaching extinction. The typhoid death rate in 1868 was 595 per million: by 1921-25 it had fallen to 11. Experience in Glasgow does not support the view that carriers are the dominant factor in the spread of the enteric fevers; missed cases were found to be more frequently in operation. The suppression of the older infections has been followed in Glasgow as elsewhere by the rise of

[1] *The Health of Glasgow, 1818-1925.* An outline by A. K. Chalmers, LL.D., M.D., etc. Glasgow: Printed by authority of the Corporation. 1930. (Roy. 8vo, pp. xviii + 451; illustrated.)

that new tribe of diseases which specially affect the central nervous system. Cerebro-spinal fever reached epidemic proportions in 1906-7, encephalitis lethargica in 1923-24, and poliomyelitis in 1928. On the coming into operation of the Public Health (Venereal Diseases) Regulations, 1917, Glasgow initiated active measures for the diagnosis and treatment of these diseases. Dr. Chalmers does not (for the time being at least) favour the general notification of venereal disease except in cases where it can be shown that third parties suffer, for example, from congenital syphilis and ophthalmia neonatorum. He thinks there is some risk that too much attention may be given to the provision of facilities for treatment and too little on the basis of avoiding exposure to infection. Of the men presenting themselves at one of the municipal treatment centres during a recent year more than half were found to be habitual libertines. "If this," he says, "is a fair sample of the patients attending male clinics elsewhere, then we must frankly recognize that the treatment centres are being put to a use foreign to the intention for which they were created, and that a corresponding proportion of their annual cost is being diverted to the furtherance of promiscuity."

Glasgow, like other cities in this country, has at times a smoky atmosphere. The amount of soot deposited is measured by means of nine soot-collecting gauges in parks and gardens. The deposit over a period of five years is quoted as 326 tons per square mile per annum; this is less than in Liverpool, Birmingham, and London, but more than in Salford. The vertical steam boiler is a frequent source of industrial smoke. Service in the prevention of industrial smoke is rendered by classes for the instruction of steam boiler firemen in the principles of coal combustion and furnace management held under the auspices of the local branch of the National Smoke Abatement League. To check domestic smoke the corporation supplies a smokeless fuel named kinoole, the radiant heat of which is claimed to be more effective than that of bituminous coal.

Though Dr. Chalmers has dealt with the health of Glasgow on the broadest lines, and made little direct reference to his personal work, the part he played in moulding the policy of the city and giving expression to it in action is much too important for any modesty to disguise, and his book stands as a worthy memorial to his distinguished record as an administrator. It will be read with appreciation by the expert and with profit by all interested in public health problems, especially those which are now emerging as a result of the coming into operation of the Local Government Acts of 1929.

BACTERIAL METABOLISM.

THE study of bacterial metabolism is one of the directions in which the chemical side of biological study is advancing most rapidly. Pasteur was the father, both of bacteriology as we know it to-day and of bacteriological chemistry, and although the main interests of bacteriology were soon diverted, in response to the needs of medicine, to the morphological and descriptive side of the subject, yet the needs of commerce served to ensure the continuation of researches into the chemical phenomena of fermentation. Progress in this direction has been steady, and if the extent to which bacteria and moulds now serve the purposes of large-scale synthetic chemistry is not widely realized, it is because manufacturers are naturally loath to court publicity for their methods, rather than because the place of bacteria in commerce is not assured. As for the importance of the nitrifying micro-organisms in agriculture, this has been established by the work of Vinogradoff; indeed, we know that upon these organisms the maintenance of plant life, and therefore of animal life, depends.

To assess fairly the relationship in which bacteriological chemistry stands to medicine is no easy task. Every researcher in bacteriology must at some time have felt the need for a fuller knowledge of the principles governing the composition of his media. In the past, these media have been made up on almost purely empirical lines, with the result that failures to obtain satisfactory results have been frequent and disheartening. The study of bacteriological chemistry is tending steadily to give us a fuller and sounder knowledge of such matters; and the application of the principles involved in the conception of "reduction potential" may well prove to be very fruitful. For medicine, however, laboratory culture media are but a means to an end. The study of infections involves the study of bacteria in a natural cultural medium, a medium, moreover, that plays no passive part. We might hope that the study of metabolic processes of bacteria would help us in more ways than one. In the first place, no other living cells lend themselves so readily to the exact control of environmental conditions. Food and oxygen supply can be measured exactly, and products accurately estimated. If from such experiments we could safely draw inferences as to the activities of animal cells, we should have at our disposal a most valuable means for studying metabolic processes. Such inferences can, however, be drawn only with great caution. In certain respects, bacteria differ widely in their behaviour from the cells of higher organisms. Thus, for example, many species of bacteria can live on media in which the sole source of nitrogen is ammonium chloride, and others can derive their energy from the oxidation of sulphur or of hydrogen. Again, we are accustomed to think of the cells of animals as, to some extent at least, capable of regulating their metabolism in response to their own needs, rather than as being dependant, as bacteria appear to be, on the materials offered to them in the medium. In some ways bacteria in culture seem to behave rather as enzyme and substrate; metabolic processes continue until either the supply of substrate is exhausted or the reactions are brought to a close and growth is stopped by concentration of end-products.

A recent monograph by Miss Marjory Stephenson[1] on the subject we have been discussing gives a most admirable view of the ground already won, and points out some of the lines along which fresh advances are likely to be made. So far as we are aware there is no other book from which may be drawn such concise and adequate information about the chief phases of bacterial metabolism. The study of bacterial metabolism must surely throw light on the relations between infecting organism and infected animal, on the production of toxin, and on the defence mechanisms of the bacteria against the bactericidal efforts of the host. The work of Heidelberger and Avery seems to point the way for investigations of this kind, since they have demonstrated the relationship between the special carbohydrate cell constituents and immunological specificity. It is known, for instance, from the work of Griffith, that cultivation of "S" pneumococci in media containing homologous antiserum results in the production of "R" types—a finding that can only mean a modification of bacterial metabolism by the antibodies present in the medium.

THE ANNUAL MEETING IN CANADA.

CANADA'S warm welcome of the visiting members of the British Medical Association, forecast in the *British Medical Journal* of July 19th, is now beginning to materialize. At the end of their sea journey they received a most cordially worded telegram from Professor Harvey Smith, the President-Elect, announcing that the hand of friendship and fraternity awaited them throughout the Dominion of Canada. The steamship *Duchess of Bedford*, conveying Professor Burgess, President of the Association, Dr. Brackenbury, Chairman of Council, and a party of members numbering 290, was boarded at Father Point by Dr. A. T. Bazin, President of the Canadian Medical Association, with Dr. Kenny, and members of the Winnipeg reception committee; unfortunately, the arrival of the ship had been delayed by fog, and so a proposed luncheon in Quebec and the Lieutenant-Governor's garden party had to be abandoned. A banquet, jointly arranged by the Canadian Medical Association organizations of the Province and City of Quebec and the medical profession of that city, was held at the Chateau Frontenac Hotel; it was attended by 400 guests. In the unavoidable absence of the Prime Minister of Quebec, eloquent speeches of welcome were delivered by the Hon. Athanase David, K.C. (Provincial Secretary of Quebec), the Mayor of that city, and Dr. Bazin, to which Professor Burgess and Dr. Brackenbury replied.

THROMBO-ANGIITIS OBLITERANS AND ARTERIO-SCLEROSIS.

THE report on arteritis of various kinds, and gangrene due to arteritis, by Dr. G. Spehl of Brussels and Professor E. Tytgat of Ghent, presented in June, 1930, to the Belgian Surgical Society[1] deals at considerable length with the pathological and therapeutic (especially surgical) questions concerning the nature of these conditions and the possibility of preventing or limiting resulting gangrene. The authors quote Leibovici's opinion that the endarteritis obliterans of von Winiwarter and Friedländer is due to juvenile atheroma, and should be distinguished from Buerger's thrombo-angiitis obliterans, but they state that this distinction is not universally accepted, and that the anatomical-clinical signs of Buerger's disease, though at first characteristic, may be less so later on. Both Buerger and Leibovici agree that in cases of arteritis there are two stages: in the first there is an inflammatory infiltration of all the coats with sometimes purulent or miliary giant-cell foci near the internal elastic lamina; in the second stage the affected vessel undergoes connective tissue obliteration by oganization of the obstructing tissue. Buerger insists that the obliterating endarteritis is due to the organization of the clot and not to a process of proliferating endarteritis as described by von Winiwarter in 1879; the condition is quite distinct, therefore, from arterio-sclerosis (atheroma). The latter may, however, in a few cases, be combined with thrombo-angiitis obliterans. In regard to the various modern pathological-anatomical and therapeutic views the authors cite sufficient authorities to render their work a kind of "critical review" of recent literature (mainly in the French language) on the whole subject, especially in regard to the efficacy and scientific bases of the methods of examination and treatment. Leriche claims that there is an "internal" stage of arteritis which precedes the subsequent "external" stage, in which the adventitia is affected, with involvement of neighbouring veins and nervous fibres and ganglia, and the periarteritic "matting." In the first stage gangrene is rare, whilst it is common when the whole thickness becomes involved; the gangrene, in his opinion, is not caused by obliteration of the arterial trunk alone, but is largely dependent on the superadded vasomotor disturbance resulting from the periarteritis. This conception constitutes the basis for the treatment of ischaemic symptoms and threatened gangrene by periarterial sympathectomy and similar operations—with the purpose of preventing the onset of gangrene and troublesome trophic (ischaemic) ulcers and pains, and with the hope of limiting the gangrenous process when it has already appeared (and thus avoiding unnecessarily extensive amputation). But according to the results obtained the value of Leriche's operation is very doubtful in cases of commencing gangrene, whether due to thrombo-angiitis obliterans or to juvenile or senile atheroma. W. A. Oppel's (1911) theory of gangrene by permanent angiospasm due to hyperadrenalinaemia (according to Ghiron adrenaline experimentally gives rise to vascular lesions comparable to those of thrombo-angiitis obliterans) has been the basis for the operation of epinephrectomy, but the authors conclude that the operation is one the physiological bases of which are not sufficiently solid, and that in spite of the good results reported by Oppel and diminished operation mortality in the hands of skilled surgeons, it can hardly take a recognized place in surgical therapeutics. Wieting's arterio-venous anastomosis is already almost forgotten as a method of treatment, and from an impartial analysis of recorded results the authors think it unnecessary to draw it back from oblivion. Diathermy appears to be of considerable use in some cases. In regard to modern methods of exploring the state of the circulation in cases of gangrene or threatened gangrene the authors regard Moskowicz's test as the best. The oscillometric method with Pachon's instrument (too little employed in England) is undoubtedly helpful. Both these methods should be used. The value of arteriography (with lipiodol, sodium iodide, or sodium bromide) is not sufficient to counterbalance its dangers and other disadvantages. Spehl and Tytgat refer to many other points regarding pathogeny, diagnosis, and treatment, for which their report and the references they give should be consulted; and those whom thrombo-angiitis obliterans attracts as a subject for study will no doubt turn with interest to the paper by Dr. Parkes Weber and two of his colleagues published in our present issue at page 279.

NOISE AND THE TOWN DWELLER.

IN an age of motor traffic, sirens, pneumatic road-drills, and intra-urban train services, it has become impossible for the city dweller to escape from noise even during his hours of sleep. Though the man whose house abuts on the railway will admit that he no longer notices the passing of a train, there can be little doubt that noise has a harmful effect on the mind, even of those who appear to be indifferent to it. The effort of concentration is considerably increased in noisy surroundings, and it has been repeatedly demonstrated that existing neurasthenia is aggravated by noise, and improved by a quiet environment. The effects are inevitably serious on young children and infants, whose nervous systems are insufficiently developed to withstand a prolonged strain; the child who has slept in the midst of uproar will awake listless and tired, and if the conditions persist his growth will suffer. The nursery schools have shown the value of a midday rest to the child who is kept awake late in a noisy and overcrowded home. In the annual report of the Willesden Urban District Council some of the difficulties in the path of legislation to reduce noise are discussed. Clearly the repair of the roads and the warnings of motor traffic are among unnecessary evils of our civilization, nor is it very easy to legislate for the suppression of the crying infant, the barking dog, or the incipient pianist. By means of a meter been found to convert sound into measurable electric waves

2,198 New In 1925-26, ... were of one apart- ments, while ...

it has been possible to determine the effects of noise on the human body. Among other results it has been found that a sound of a given magnitude produces a reaction of fear in the newborn infant, that noise raises the blood pressure in the adult, and that a degree of noise insufficient to waken a sleeping person will cause the muscles to contract and to remain tense for as long as thirty minutes before they relax. Deafness, dizziness, and headache are the lot of those who earn their livelihood by boiler-making or cotton-weaving, and it has been estimated that for normal persons it requires 19 per cent. more energy to perform duties in noisy surroundings than to perform the same duties in a quiet environment; the strain on those whose mental or physical health is not normal can be imagined. The Middlesex County Council has provided certain by-laws to reduce street noises, but these are directed chiefly against street criers and singers, and cannot affect traffic noise. The fact that many of our large hospitals are situated in the midst of busy thoroughfares makes the problem more urgent, since noise is clearly on the increase. Into the Middlesex County Council Bill, which is to come before Parliament next session, a clause has been introduced to give the local authorities the same powers with reference to noise that they have with reference to nuisance under the Public Health Act. This will apply to excessive, unreasonable, or unnecessary noise, wherever it is injurious to health, or where it is capable of being mitigated, having regard to all the circumstances, such as cost. In New York the Noise Abatement Commission has suggested fines for those who create unnecessary noise; sound-proof buildings and zones of silence round hospitals have also been advocated. A greater hope of prevention lies in removal of the cause by the provision of silencers, abolition of strident horns, destruction of worn-out machines, the use of pneumatic tyres, and the substitution of electric welding for riveting. It is estimated that at least 75 per cent. of street noise could be abolished by these measures, and a movement in favour of noise abatement would do much to pave the way for the necessary legislation.

CONGRESS OF MILITARY MEDICINE. AN AMERICAN ECHO.

THE official report of the fifth International Congress of Military Medicine, which was held in London in May, 1929, has already been published, but the American member of the permanent committee of the congress, Commander W. S. Bainbridge of the United States Naval Reserve, has compiled a shorter report[1] principally for American readers. He has summarized the congress discussions, and he adds some descriptive touches, which, with the illustrations, as the foreword says, "all but take you to the meeting." Reproductions of the photographs of the personalities and events of the congress greatly brighten up the pages; the only failure is a sheet reproduction of the group of the delegates taken in the courtyard of the British Medical Association House, in which it is very difficult to recognize a single figure. Resplendent uniforms and decorations, while brilliant to survey, are apt to deteriorate sadly under the combined processes of photography and block-making. The compiler has done his work well, and the opinions and recommendations put forward during some very useful sessions are adequately set out, he carries the story a stage further, for he was the member of the committee appointed to visit, after the congress, certain European countries with a view to completing the work which had started in London, and also to ensure that good national delegations will be sent to the sixth congress at Budapest next year. He states that with this object in view he has held conferences with the chiefs of the medical services and other important people of seventeen nations. One remarkable personage he visited, and on whom he bestowed an American decoration, was General Ludvik Fisher, Surgeon-General of Czechoslovakia, who has created in his country a medical service which now embraces nineteen hospitals and seven spas. General Fisher practised for many years as a surgeon in Chicago, but, always a Czech at heart, he returned to help his country in the war, and helped her so effectively that the old Austrian Government put a price on his capture, though the new Austrian Government has done him honour. Commander Bainbridge believes that excellent as was the London congress, when forty nations participated (as against twenty when the first congress was held in Belgium in 1921), next year's event at Budapest will surpass that record. For the first time Germany will be sending delegates to what in its origin was a conference of the military medical services of the allied and associated Powers. The report concludes with a pleasing tribute to British hospitality, and an appreciation of some of those who had most to do with the arrangements in London, especially the president, Lieut.-General Sir Matthew Fell, and the energetic organizing secretary, Major A. D. Stirling.

[1] Report on the Fifth International Congress of Military Medicine and Pharmacy, London, May, 1929. By W. S. Bainbridge, United States Naval Reserve. Collegiate Press, Menasha, Wis.

GIZA MEMORIAL OPHTHALMIC LABORATORY.

IT might be anticipated that the centres of medical teaching and research which are scattered throughout the more distant parts of the Empire, being to some extent isolated and cut off from the stimulation of close contact with the scientific thought of the Mother Country, would tend to fall behind in originality and enthusiasm. This at any rate cannot be said of the Giza Memorial Ophthalmic Laboratory at Cairo, to judge by the last report we have received of the work done there. The laboratory forms a memorial to the men of the Egyptian Labour Corps and Camel Transport Corps who died while serving the armies of the Empire during the great war. It may be remembered that the funds for its erection were voted in 1921 by the Imperial War Graves Commission in London, and the cost of its equipment was granted by the Egyptian Government. The result has been the foundation of one of the finest ophthalmological laboratories in the world, and its existence and success were largely dependent upon the energy and enthusiasm of Mr MacCallan, who suggested and inaugurated the scheme. There is now a well-equipped laboratory for pathology and bacteriology, provided with a library and the staff for a course of post-graduate training in the diseases of the eye in association with the Ophthalmological Hospital at Giza. The work of the laboratory shows a very large amount of interesting clinical material, and the cases described in some thirty pages. The most interesting part of the report however deals with the research work which the laboratory has undertaken under the direction of Mr Rowland Wilson. As would be anticipated in the laboratory, a considerable amount of attention is given to trachoma. With regard to the etiology of this disease the results have been somewhat negative and have tended to decrease the importance of the bodies of Provazek and Lindner, as well as the specific organisms which have been cited from time to time as being etiological factors in the disease. A long paper is contributed on the [illegible] of follicular conjunctivitis in monkeys, and it is evident that the appearances resembling this disease that occur in these animals have not been proved to be definitely related to trachoma. The observations which are recorded on the difficulties which have been met in determining the pathogenicity of the various organisms discovered very definitely that the results of investigations [illegible] recently carried out by Noguchi require further careful

INTERNATIONAL CONGRESS OF DERMATOLOGY AND SYPHILOLOGY.

THE eighth International Congress of Dermatology and Syphilology was held at Copenhagen from August 5th to 8th, almost a thousand members and their friends assembled for its formal opening by the president, Professor RASCH, in the ceremonial hall of the Christiansborg Palace. The King of Denmark was present, and after speeches of welcome by the Prime Minister, the mayor of Copenhagen and others, the president presented some of the principal foreign delegates.

The first subject of discussion was the etiology and pathogenesis of eczema. Professors DARIER (Paris) and JADASSOHN (Breslau) analysed the present state of knowledge, both tending to emphasize the importance of the phenomena of sensitization, as did many of the subsequent contributors. Dr. ARTHUR WHITFIELD (London) submitted an interesting communication on the subject of autosensitization. Professor SABOURAUD (Paris) pointed out that in reality the whole problem was the determination why some individuals were sensitive, while the majority were not. The second day was devoted by the dermatologists to the discussion of papers of varying degrees of interest, among the most important being one contributed by Dr. BARBER (London) on recent advances in the investigation and treatment of allergic eruptions. It is possible that he and his colleague Dr. Oriel have isolated a specific antigen upon which these eruptions depend. The early morning of the third day was spent in studying a highly interesting series of clinical cases collected by the local dermatologists, among which various forms of sarcoids and a large number of cases of Darier's disease figured prominently. Subsequently the congress members and their friends were transported in motor charabancs to Marienlyst, one of the delightful little seaside resorts in the neighbourhood of Copenhagen, where lunch was provided, after which all visited the Castle of Cronborg and the ramparts traditionally associated with the ghost of Hamlet's father, they were then taken through charming scenery to the palace of Friedrichsborg, which was also inspected, and back home to Copenhagen. A meeting on August 9th was devoted to the consideration of the treatment of tuberculosis of the skin, the opening paper being delivered by Professor AXEL REYN, who has been continuing the great work initiated by Finsen at the institute which bears his name. The chief point of general interest which emerged from the discussion was that there was a fairly general agreement that the new dietetic treatment of lupus, consisting in the employment of food acid in character and free from ordinary salt although not without a favourable influence on the disease was quite insufficient to cure it.

Two days were spent by the syphilologists in considering the more interesting and obscure phases of that protean complaint. It was decided that an important matter for investigation was the case of patients who in spite of careful and persistent treatment continued to have a positive Wassermann reaction. Should treatment be continued indefinitely, or did a time come when it was no longer necessary? Were such patients more liable to relapse than those whose reactions ultimately became negative? Secondly, it was decided that it would be desirable that all nations should adopt the standard notation laid down by the organization of the League of Nations in describing the degree of positivity of the Wassermann reaction. Great Britain had adopted this notation so long ago as 1923, but many other nations had failed to do so. It was felt that if clinicians would demand the adoption of the standard notation the pathologists would be compelled to fall into line. The last day of the congress was entirely devoted to listening to the remaining separate papers. Since in addition to the set discussions there were no fewer than 177 papers accepted by the committee of the congress, it will be readily appreciated that hard work and strict timekeeping were necessary in order that the programme should be completed by Saturday evening, August 10th. This was accomplished, thanks to the masterly organization and excellent arrangements of the local committee. The general secretary, Dr. Svend Lomholt, was indefatigable and ubiquitous and his efforts were most ably seconded by his colleagues, Drs. Kissmeyer and Haxthausen.

A special word of appreciation is due to the lavish hospitality with which the members of the congress and their friends were overwhelmed. Each evening there was a social function, and during the day arrangements were made to entertain the members' wives while their husbands were engaged in the scientific work of the congress. The social side of the meeting culminated in a banquet on Friday evening, this gave the foreign representatives an opportunity to congratulate the Danish dermatologists on the success of their arrangements and to return thanks for the hospitality which they had received. It was generally agreed that Copenhagen had set a high standard for other cities to attempt in the management of international congresses.

STORAGE OF X-RAY FILMS.

THE X-RAY AND RADIUM PROTECTION COMMITTEE'S RECOMMENDATIONS.

AFTER the disaster at the Cleveland Hospital, Ohio, last year, the British X-Ray and Radium Protection Committee considered the whole matter and issued a memorandum on the handling and storage of x-ray films (*British Medical Journal*, November 16th, 1929, p. 923). At the suggestion of Dr. Stanley Melville, honorary (medical) secretary of the committee, and at the request of a number of correspondents, we now republish the specific recommendations therein set out.

School Medical Inspection in the Irish Free State.

In the report of the Department of Education (Irish Free State) a survey is made of the *medical inspection of* school children. The report states that medical inspections in the Dublin schools during the year revealed 10,642 defects requiring treatment, and 4,057 necessitating observation—a total of 14,699 defects. *Decayed teeth* accounted for 6,996 of this total; there were 2,293 cases of enlarged *or septic tonsils and adenoids*, and 2,240 cases of diseases of the eye. The parents of children needing *immediate treatment* were advised to make use of the city hospitals, the choice of the institution being left to the parents themselves. The extent to which this arrangement was taken advantage of is revealed by the returns received from the hospitals. During 1929 the number of children treated for defective vision was 986, and of these 854 were supplied with glasses free of charge; 350 children were treated for external eye disease, 1,108 children had septic tonsils or adenoids removed; and 3,718 children were treated for defective teeth. In Cork city, where a scheme of medical inspection has been in operation since 1924, the number of school children examined during 1928 was 2,208, and the following defects were noted: nose and throat, 453; defective vision and affections of the eyes, 633; and dental caries or other defects, 3,531. In the borough of Clonmel six schools had come under the operation of the scheme of school medical service, and thirteen inspections were made during 1929. The number of children inspected was 1,483, and the following figures are recorded: number of children suffering from defective teeth, 940, from goitre, 26; from enlarged tonsils and adenoids, 185; from tuberculosis, 3; from serious defects, 6; from malnutrition, 12; and from anæmia, 31. The number of children badly kept was 25. In County Cork 10,829 children were *examined in 1929*; of these, 6,133 individual children, or 56·6 per cent., *suffered from defects which required treatment or observation*. A total of 9,683 defects were discovered, of which 6,238 *required treatment*, 2,754 children (25·4 per cent of the total number examined) suffered from more than one defect. There were 2,899 cases of dental disease, 1,721 cases of nose or throat diseases, 989 cases of defective vision (including squint), 817 cases of uncleanliness, and 659 cases of malnutrition. Only a trifling number of parents attended at the inspection, but it is stated that there had been evidence at the re-inspection of various schools of considerable remedying or improvement of the defects noted at previous inspections. In County Kildare the inspections were very well received. Over 95 per cent of the children actually attending the schools were presented for examination, and the parents of nearly 50 per cent. of the children examined were present at the inspections. The examinations disclosed the following conditions: defective teeth, 3,081; enlarged tonsils and adenoids, 1,212, defects of the eye, 1,094; and malnutrition 730. In County Louth the results of the inspection showed dental caries, 51 per cent.; diseased tonsils and adenoids requiring special treatment, 16 per cent.; minor throat conditions, 13 per cent.; defective vision, 6.3 per cent.; squint, 1.9 per cent.; and other diseases of the eye, 1·1 per cent.

Northern Dispensary Doctors and Medical Benefits.

In view of the early introduction of medical benefits in Northern Ireland the medical officers of certain Northern dispensary districts desire an alteration of hours. The matter was referred to at the meeting of the Newtownards Board of Guardians recently, when a suggestion was made by the medical officers of the various dispensary districts for a change in the dispensary hours. The guardians, however, in a subsequent discussion, dealt with the matter as though the dispensary doctors had asked for a reduction in the hours of attendance; owing to this *misunderstanding* it was suggested that the doctors should accept reduced salaries if granted a reduction in the hours of attendance. The clerk pointed out that the doctors were making no application for a reduction in the number of hours, but only that their times of attendance should be altered.

England and Wales.

London Ambulance Service: Conveyance of Maternity Cases.

Now that the London County Council is responsible for a combined ambulance service, including its own accident service and the services lately controlled by the Metropolitan Asylums Board and some of the boards of guardians, the question of the arrangements for the conveyance of maternity *patients to hospital*, has been considered. The "accident" ambulances have hitherto carried parturient women free of cost, if the case is an urgent one, and provided that either a doctor or a midwife accompanied the patient. They have also carried non-urgent maternity patients between the hours of 11 p.m. and 8 a.m. on the *production of letters of admission to the maternity hospital*, in such cases it is sufficient for a female friend to *accompany the patient. It does not appear to the Council* that there is any evidence that a day-time ambulance *service for non-urgent maternity patients is needed.*" Six borough councils have asked that such a service should be instituted, but beyond a general expression of opinion they have brought forward very few supporting circumstances, while nine borough councils considered that there was no need for such an extension. It is not thought advisable at present to make the general ambulance service, which deals with the transport of patients, infectious and non-infectious, to and from the Council's hospitals and institutions, available for non-urgent maternity patients, though this will probably come about in time after the necessary rearrangements have been completed. Meanwhile any arrangement for the conveyance at the public cost of non-urgent maternity patients during the day-time is regarded as the responsibility of the several metropolitan borough councils as authorities under the Maternity and Child Welfare Act. The London County Council is prepared to place its ambulance service at the disposal of such patients if a metropolitan borough council desires it, provided it undertakes to pay an agreed sum, and that the service is limited to patients approved by the borough medical officer of health.

Co-ordinated Hospital Service for Leeds.

A scheme has been approved for the utilization of the Poor Law institutions of Leeds for general medical treatment in accordance with the provisions of the Local Government Act. The Poor Law hospitals of Leeds are three in number—namely St. James's, St. Mary's (Bramley), and the Rothwell Infirmary; they will be transferred from the public assistance committee to the health committee to form part of a public hospital service [illegible] congestion in the voluntary hospitals or the [illegible] relieved. St. Mary's Hospital is old [illegible] unsuitable for modern purposes. St. James's H[illegible] on the other hand is [illegible] and staff, is capable with certain [illegible] adapted for the reception of the [illegible] has the advantage of a central situa[illegible] has been managed by the guardia[illegible] lines of a general hospital [illegible] *surgeons of consulting* rank all exce[illegible] on the staff of the Leeds General Infir[illegible] *X-ray and ultra-violet* radiation apparatus has [illegible] installed there is an operating theatre, and also a laboratory with a trained pathologist. It is proposed to transfer a proportion of the infirm sick at present in St. James's Hospital to the other two institutions, so as to make available a surplus of beds to meet the demand for the accommodation of the acutely sick. An out-patient department will also be instituted at St. James's Hospital which will deal only with patients who have already received treatment in the hospital and still require a certain amount of after-care. Such a department, it is thought, [illegible] only add to the effectiveness of the treatment but will have the effect of curtailing the period of residence of some patients, and thus of indirectly increasing the total bed accommodation. Under the rearrangement St. James's

complications comprised the following: 21 cases of accidental haemorrhage, 6 of placenta praevia, 17 of puerperal pyrexia, and 3 deaths. One of the deaths was in an unbooked case of abortion with severe concealed haemorrhage at twenty-four weeks gestation; another was in a patient who was admitted at thirty-two weeks gestation with severe bronchitis and albuminuria, and the third in a woman who had been under the care of her own doctor for influenza and died at the moment of delivery. There were 32 neo-natal deaths—26 among infants born in the hospital, 6 on the district; 49 infants were stillborn—36 in the hospital, 13 on the district. Of the 1,262 survivors, 1,185 were over birth weight on discharge, 62 were equal to birth weight, and 15 were under birth weight. During the year the attendances at the ante-natal clinic totalled 7,811, 1,379 of these being made to the medical officer's clinic. The following complications due to childbearing were treated during pregnancy: 56 cases of albuminuria, of which 33 were treated in hospitals and 23 at home, 1 case of hyperemesis, 5 of pyelonephritis, 3 of bacilluria, 4 of chronic nephritis, 14 of purulent vaginitis, and 27 of dangerous varicose veins. In addition, 63 cases of diseases not due to childbearing were treated at the ante-natal department.

Cumberland Infirmary Extensions.

Two new wards for in-patients and a pathology department were opened at the Cumberland Infirmary on July 31st by Lord Howard of Penrith, with Mr. W. Theodore Carr, president of the infirmary, in the chair. The wards have been named the "Balfour Paul," and "Woodside" wards, the former being presented by members of the family of the late Mr. C Balfour Paul—for many years honorary surgeon to the Cumberland Infirmary—and the latter by Mr. Andrew Gibson, Woodside, Carlisle. The pathology department has been erected out of funds provided by the Carlisle Pageant Committee, and generous contributions have been made for its maintenance, including £1,500 from Mr. P. H. Holt of Yrithbie, Annan, who originally initiated the scheme. Referring to the work that had been done at the infirmary since the foundation stone of the central building had been laid over ninety years ago, the president said that the institution and its staff had played a very important part in the development of antiseptic surgery, and in the evolution of the use of anaesthetics. It was in Carlisle that Lister had accidentally discovered that carbolic acid was being used to take away the smell of the local sewage, a fact which had suggested its application in surgical operations. Since 1919 extensive improvement had been made in the facilities for the treatment of disease and injury so that the hospital was now among the most efficient in the country. The president expressed the hope that it might soon become a school for nurses, and provide the medical profession with opportunities for post-graduate study. With the opening of the new wards the extension scheme of the infirmary has now been completed, at a total cost of £55,000. Each of the new wards accommodates fourteen beds and is of fire-proof construction, being built of bricks and roughcasting, with slated and asphalted roofs. The floors are of polished pitch pine, and the absence of corners prevents the accumulation of dust. Both have small independent wards attached, one with two beds and the other with three, constructed on the same style as the main wards. Near the Balfour Paul ward a chemical room has been fitted up, and a bed-lift can be operated between the new ward corridor and the ground floor passage. A special room, equipped with steel lockers, has been set apart for storing patients' clothing. The new wards are connected by a corridor with the infirmary buildings, and by a flight of steps with the out-patients' department. The pathology department, which is a building about 70 feet long and 40 feet wide, has been erected on an independent site to the north of the infirmary. It has a well-equipped laboratory, and a balance and a sterilizing room with the necessary apparatus in addition to offices and stores. Gas, water, and electric light and power fittings are all of stainless metal. To commemorate the services of Mr James Carr, who was a member of the infirmary governors for many years, a special ward for nurses—to be known as the Margaret Carr ward—has been erected in conjunction with the Balfour Paul and Woodside wards. It contains three beds, which will be reserved for sick nurses. The Page ward, which is now in course of extension, will ultimately be divided into two sections, one for men and the other for women, where special treatment will be given for diseases of the ear, nose, and throat. The alterations are estimated to cost about £2,000.

Artificial Light Treatment for Tuberculosis in Lancashire.

In a report, recently presented to the Lancashire County Council, Dr. G. Lissant Cox, central tuberculosis officer gives an account of the treatment of non-pulmonary tuberculosis during 1929 at twelve of the county tuberculosis dispensaries where artificial light centres have been established. The apparatus employed in the majority of cases consisted of two carbon arc lamps, one of a sun ray pattern for general treatment, and a Kromayer mercury vapour lamp for local treatment. In obstinate cases ancillary forms of treatment, such as curetting, cauterizing, and aspiration, were found helpful. Dr. Cox concludes from a survey of the year's work that the artificial light treatment continues to give favourable results, particularly in cases of tuberculosis of the skin, and tuberculous adenitis with abscess formation and skin involvement. 60 patients suffering from lupus and scrofuloderma were cured out of 109 who began treatment during the year, while 87 out of 133 were treated with apparent success for the second condition during the same period. In 60 cases of skin disease which became "quiescent and apparently cured," the average duration of the disease before the patients began light treatment was ten years eight months; treatment was given for ten and a third months on an average. The report draws attention to the fact that of 252 patients who showed apparent recovery on finishing treatment in 1929 the consultant tuberculosis officers would normally have recommended 211 for treatment at hospitals. By their treatment at dispensary light centres about £2,552 is estimated to have been saved. It is also emphasized that most of the patients were able to continue their normal occupations during the course of treatment. Patients attending the centres during 1929 numbered 842, as compared with 726 in the preceding year.

cost only £2 2s., it would cost the community 10,000 guineas to save one life.

This is a very heavy burden to put upon a country already tottering on the verge of bankruptcy. The benefit that might be derived from such colossal expenditure is, on the available evidence, too slight to warrant the risk of a financial catastrophe, for bankrupt England would become a shambles, compared to which the Reign of Terror would seem as peaceful as the annual outing of a philanthropic society.—I am, etc.,

Rutland, Aug. 16th. G. H. CRISP.

TECHNIQUE OF INJECTING VARICOSE VEINS

SIR,—As the writer of a brief letter, some three years ago, to the *Journal* recommending the use of intravenous sclerosing solutions for varicose veins, more especially in treating varicose ulcers and dermatitis, and one who has used this method extensively, I have been very interested in the recent communications on this subject appearing in the last few issues. I rarely encountered cases which did not respond to quinine urethane solution, if given in sufficient amount, but in those that did not do so I found that sodium morrhuate in 10 per cent. solution with phenol 0·5 per cent. invariably worked.

Regarding the occurrence of any untoward symptoms, such as hypogastric cramp-like pains (? uterine) or fainting, I have had none of the former with sodium morrhuate, but in a few faintness came on in a few seconds after injection with both these solutions when given to the same patients. In such I think this is often due, especially in using sodium morrhuate to fear or apprehension in nervous persons.

I prefer to have the patient sitting on an ordinary chair, as mentioned by Dr. Scott in his article in the *Journal* of July 12th, and to make the injections from below upwards. By this means it is much easier to enter the vein and, what is more important, to be sure that the needle remains in it during the injection (by withdrawing the plunger of the syringe and noting if blood flows into the barrel). If one performs the injection in this position, when the patient has not been walking about too much just previously, or has been wearing supporting bandages and removes these immediately on sitting down, then I find there is just sufficient distension of the veins to permit easy access, and the solution injected is not too much diluted by the residual blood in the vein to be effective. I now prefer 10 per cent. sodium morrhuate, since I find it more satisfactory than the 5 per cent. solution. The 5 per cent. strength is useful for small veins. Probably the reason for my considering the stronger solution more satisfactory is that owing to my usually injecting the veins when partially filled with blood, as above, the solution becomes too diluted to cause a chemical endovenitis unless I use the stronger one. For varicose ulcers, and some cases of varicose dermatitis, I find a local dressing of "anasthesine" (Hoechst) often helps to allay the pain and irritation while the veins concerned are being dealt with.

One other point that I think is of importance in treating patients sitting on a chair, when using sodium morrhuate solution, is not to apply any constricting bandage to the limb for at least three hours afterwards, but merely to seal the puncture wound. By putting on a tight bandage at once after the injection the fluid thus introduced is apparently often forced out of the veins before it has had sufficient time to affect their endothelium, or it only remains in too weak a dilution to be effective. After this period a bandage may be applied, it helps to cause the walls of the veins to adhere and obliterate their lumen. When using quinine urethane solution I give the injection sitting; after a few seconds I raise the limb to a horizontal position, retain it there about a minute, and then let it drop, repeating this procedure two or three times before bandaging the leg up.

I find about 2 c.cm. of 10 per cent. sodium morrhuate solution for each injection to be an average amount to give, and frequently give 10 c.cm. altogether at one sitting. With reference to its main advantages as compared with sodium salicylate or quinine urethane solutions, they are five in number—namely (1) less toxic, (2) much less bruising or tendency to haematoma resulting from its use, (3) if any escapes into the perivenous tissues there is less likelihood of a slough resulting, (4) produces a similar end-result quicker than either of the other two, (5) owing to the oily nature of sodium morrhuate it is more suitable for a lubricant for the piston of a syringe. After use I cleanse the syringe with ordinary water and then put it in "surgical spirit" (John Richardson and Co., Leicester), this fluid prevents corrosion and discoloration as occurs with ordinary methylated spirit, owing to there being some oleum ricini in the former. I do not use a tourniquet, except in rare cases.

If any fluid should escape into the surrounding tissues during the injection, as evinced by the patient complaining of a burning sensation or a stinging pain at the site, I find the best thing to do, in order to prevent a slough resulting, is to leave the needle *in situ*. I first endeavour to aspirate the fluid injected, usually without much success, then to inject some normal saline solution quickly and aspirate this if possible in a few seconds. I repeat the process two or three times, and then withdraw the needle, letting the blood escape freely from the puncture wound for about a minute. Finally, I massage the part involved for five minutes. By this means an effort is made to remove rapidly or else dilute any remaining fluid as quickly as possible.

One can generally tell almost at once after injection into a vein whether it is going to be successful or otherwise, since the patient mentions, usually within a few minutes, something in the veins, variously described as warm running water, pins and needles, etc. With sodium morrhuate solution one can frequently see and feel the area of vein that is going to be affected by the injection as it swells up and becomes hard to the touch. I noted when using quinine urethane solution that occasionally fine fibrillary muscular twitchings occurred over the area where the patient stated he felt "pins and needles," etc., more especially does this happen in the feet. I have not as yet, used lithium salicylate solution 30 per cent. as mentioned by Dr. Scott, and I would like to know if he finds it to be locally very toxic should any escape into the perivenous tissues. At times, however careful one may be, some of the solution injected will migrate into surrounding parts, probably owing to thin-walled veins and loss of their normal structure.—I am, etc.,

Leicester, July 27th. T. A. T. SILCOCK, M.D., D.P.H.

SUBACUTE COMBINED DEGENERATION OF THE CORD

SIR,—The names of Professor Gulland and myself appear frequently in the very interesting article by Dr. J. P. McGowan on subacute combined degeneration of the cord in primary anaemia of the fowl in the *Journal* of August 9th (p. 204). I should therefore be obliged, in Professor Gulland's absence, if you would publish the following observations by myself on it.

Dr. McGowan has reported the occurrence of marked sideriotic changes and of alterations (quantitative and qualitative) in the bone-marrow in seven cases of subacute combined degeneration of the spinal cord in fowls. In only one of these cases was any marked anaemia present. I have had no experience of pernicious anaemia in fowls, but this finding would be remarkable in the human subject, in whom such bone-marrow abnormality is invariably accompanied by a high degree of anaemia. Further siderosis in the human subject is evidence either of excessive blood destruction or of defective blood formation, and in either case clear evidence of anaemia is present during life. In pernicious anaemia during the remission that is when little or no anaemia is present) the bone-marrow returns to the normoblastic mode of blood formation, and becomes indistinguishable from marrow found in healthy patients. At a necropsy last year on a patient suffering from pernicious anaemia, who had died as the result of an accident at a time when he had a practically normal blood count, no siderosis was found in any of the organs, and a diagnosis of pernicious anaemia could never have been made from the post-mortem findings.

With regard to the central nervous system changes described by Dr. McGowan, it is impossible to say from his illustrations whether they are analogous to the changes occurring in the human being. The method used for staining the sections was Marchi's, which, although excellent for showing degenerating myelin, is of no value for demonstrating the presence or absence of astrocytic activity and neuroglial formation. Weigert's neuroglial fibril stain, or Cajal's gold chloride impregnation method, is required for this purpose. Accordingly, unless this has been carried out (and Dr. McGowan makes no statement to this effect) it is impossible to attach much weight to the statement that no neuroglial proliferation was present. From what has been stated, the question whether the blood and central nervous system changes occurring in fowls are identical with those of human pernicious anaemia must for the present remain doubtful.

Dr. McGowan's hypothesis regarding the etiology of pernicious anaemia may be summarized thus. The specific type of bone-marrow change in pernicious anaemia is produced by a toxin, and the changes in the central nervous system, stomach, and liver are the result of anoxaemia of these tissues, consequent upon the anaemia. The toxin theory of pernicious anaemia is one of the oldest theories existing, and one which I, as a bacteriologist, always hoped would prove to be the correct one. After several years' work on the intestinal flora in cases of pernicious anaemia, and after a careful review of the literature dealing with the toxin theory, we were forced to discard this view owing to the absence of any proof as to the nature, source, and mode of action of the hypothetical toxin. Dr. McGowan has returned to the toxin theory without attempting to bring forward any evidence on which to base his contention. He agrees with our statement that in the liver there is present an agent which is necessary for normal blood formation. The essential point of his contention, however, is that the primary cause of the upset of marrow function met with in pernicious anaemia is a toxin, and that the amount of specific factor produced by the still normal liver is insufficient to control this abnormal marrow. Further liver deficiency may now, he admits, be brought about by the anaemia resulting from faulty marrow function, and thus a vicious circle is established. It appears simpler to explain the marrow changes by a mere deficiency of the specific factor, without the addition of a hypothetical toxin of whose existence we have no evidence. That a deficiency of the specific factor is the essential feature in the production of pernicious anaemia is shown by the fact that replacement therapy causes a return to normal blood formation. The problem whether the original site of manufacture of the specific factor is the liver itself, as suggested by Dr. McGowan, or whether the deficiency is due to defective protein metabolism in the stomach, as suggested by Castle, is one which we have discussed in full in our monograph, and which still remains unsettled. We are inclined strongly, however, to the latter hypothesis, and believe that the specific factor is merely stored in glandular organs, particularly in the liver (because of its size and of its normal storage functions), and also in the stomach and kidneys.

Dr. McGowan states that the pathological changes in the spinal cord and stomach are the result of an anoxaemia, secondary to bone-marrow changes. This appears to us to be in direct conflict with certain fundamental facts universally recognized by all who have made a study of pernicious anaemia in human beings. Dealing first with the central nervous system, it is beyond dispute that severe cases of subacute combined degeneration occur in which the blood count and blood picture may be normal, and which have never previously shown any symptoms or signs of anaemia. Accordingly, if anoxaemia is present in such cases, it must be of relatively small degree. In many of these cases there is no history of any previous period of any kind of ill-health whatsoever. We cannot agree with the analogy drawn by Dr. McGowan from the case of the fowl, in which apparently a considerable degree of anaemia may exist for long periods without being recognized. We believe that the human subject suffering from any pronounced degree of anaemia would be recognized, or would recognize himself, as being definitely out of health, though admittedly his illness might not be recognized as "pernicious anaemia." On the other hand, we have all seen large numbers of cases of pernicious anaemia which have reached either rapidly or slowly a high degree of oligocythaemia (one million or less red blood corpuscles per c.mm.), without any symptoms or signs of central nervous system disease being present.

In his present paper Dr. McGowan describes fowls with subacute combined degeneration of the cord, yet with little or no anaemia, and in past papers he has frequently reported cases of severely anaemic fowls with no central nervous system changes. These facts clearly show that there is no relation between the degree of anaemia and the degree of central nervous system degeneration, and are accordingly in direct opposition to his hypothesis.

The explanation of achlorhydria as a result of anoxaemia is also fraught with difficulty. Dr. McGowan claims that in anaemic pigs there occurs a lowering of the alkali reserve of the blood, accompanied by achlorhydria. That this may be so we do not doubt, but that anaemia *per se* is the cause of the achlorhydria in pernicious anaemia is contraindicated by the following facts. Many patients who later develop pernicious anaemia are definitely known to have been achlorhydric for a very long period—in some cases since childhood. Also, the percentage of children with achlorhydria born of pernicious anaemia parents is far higher than that among persons of their own age born of normal parents. This is also true of children born of parents suffering from subacute combined degeneration of the cord. Such patients in the prepernicious anaemia stage have a normal blood count, and in consequence it is difficult to understand on what basis Dr. McGowan can suggest that anoxaemia is present. It would appear remarkable that the anoxaemia which, in his view, must have been responsible for causing the achlorhydria should, although existing over such a prolonged period, have caused no damage to the central nervous system.

It was for the foregoing reasons, and particularly because of the absence of relationship between the degree of anaemia and the degree of central nervous system involvement, that we were forced to enlist the help of the constitutional element in explaining the disease. Moreover, we stated that we were fully aware of the danger of too readily invoking "diathesis" at the expense of experimental and clinical investigation as a means of explanation. Dr. McGowan states that if a constitutional predisposition can be held responsible for the lesions of the central nervous system in pernicious anaemia, it can logically be held responsible "for the sequelae and complications of each and every individual disease in which complications and sequelae are irregular in their occurrence." Far from disagreeing with this point of view, we would state that this seems the only logical explanation in many such cases. It is, in short, merely one way of stating the accepted doctrine of "the seed and the soil," and emphasizing the importance of natural immunity.

Dr. McGowan is to be congratulated on his careful researches into the blood and central nervous system changes occurring in fowls, which must prove extremely interesting and stimulating to all working on the subject of human pernicious anaemia. We feel, however, that to return to the "toxin" hypothesis of pernicious anaemia, especially when unsupported by any facts regarding the nature and source of the toxin, is to introduce further confusion into an already confused subject. Nor do we feel that Dr. McGowan's explanation of the tissue changes in the stomach and spinal cord, as being due to anoxaemia, is in keeping with the well-proven facts stated above.—I am, etc.,

STANLEY DAVIDSON, M D , F R C P.
Department of Medicine, University of Edinburgh, Aug. 13th.

SIR,—Dr. J. P. McGowan has described a disease occurring in the fowl in which anaemia and degenerative changes in the spinal cord occur. It is difficult to understand how, with no other evidence than his observations on seven fowls, he can reject the mass of evidence collected in the last ten years, which proves that achlorhydria is a predisposing cause of pernicious anaemia and subacute combined degeneration of the cord, and that neither the

achlorhydria nor the cord degeneration is a result of the anæmia. The frequent familial occurrences of achylia gastrica, pernicious anæmia, and combined degeneration of the cord, either separately or together, is also denied by him, apparently for no other reason than that in the absence of personal experience of the disease except in fowls, he has not paid attention to the extensive literature on the subject.—I am, etc.,

New Lodge Clinic, Windsor Forest, Aug. 13th. ARTHUR F. HURST.

ETIOLOGY OF PUERPERAL SEPSIS.

SIR,—Dr. Colebrook's paper in the *Journal* of July 26th (p. 134) resuscitates and confirms Schottmuller's well-known views on the occurrence of anaerobic streptococcal infection in puerperal fever. In Dr. Colebrook's opinion one-half at least of the cases of puerperal fever are to be attributed to these anaerobes. To the practising obstetrician it may well appear that yet another group has been added to the terrifying array of pathogenic streptococci. Dr. Colebrook's observations, however, are open to a different interpretation.

The outstanding clinical characteristic of the group of 18 cases described is thrombo-phlebitis of the pelvic veins. A notoriously dangerous procedure, intrauterine manipulation, is recorded in 10 out of 13 cases; clinical details are lacking in the remainder. The cases are not contagious. The anaerobic streptococci cultivated by Dr. Colebrook from the blood are mixed with other organisms in half the cases. Our personal experience of these anaerobic streptococci indicates that they are normal saprophytic inhabitants of the genital tract and are of low pathogenicity.

May it not be that the provocative factor is intrauterine manipulation, or trauma, and that the infection by various endogenous streptococci and other organisms is a sequel?

Are we not therefore considering the bacteriology of a familiar and troublesome clinical condition, long recognized by obstetricians as puerperal thrombo-phlebitis, rather than a new form of puerperal fever due to a distinct and, to this extent, specific group of streptococci?—We are, etc.,

R. R. ARMSTRONG.
H. BURT-WHITE.

London, E.C.1, Aug. 10th.

SIR,—Much is being published about puerperal and its causes, but it appears to me that one chief causes has been overlooked—namely, the unfit many of the young women of to-day for child-b The dress worn by women nowadays is so scant then physical development is easily seen, and it is able how many of them have the small pelvis charac of the male. Under this condition pregnancy small child in early days may be satisfactory, bu on, when full development has taken place and joints have become more fixed, is it surprising tha injury is done to internal parts during parturitic that septic developments result?

I am acquainted with the case of a young suffering from congenital hip deformity, who friendly with a young man, before deciding on an ment she consulted a woman doctor, was examine told she could safely marry. I think this pre-m examination is of equal importance, in certain cas pre-natal examination, and that its practice woul the severe criticisms now being passed on doct nurses.—I am, etc.,

London, S.W.2, Aug. 11th.

IDIOPATHIC HÆMORRHAGE IN THE NEW

SIR,—The interesting communication by Drs. Boyd and J. A. Elliot in the *Journal* of Aug (p. 213) prompts me to draw attention to an ar haemorrhage in the newborn in *Modern Techn Treatment* (vol. ii, p. 69), and to mention three melæna neonatorum which I have seen. The fi in the post-mortem room of the Edinburgh Hosp Sick Children, and the origin of the bleeding was f be a small polypus on the mucosa of the duodenum had become partly separated at its base.

The other two cases occurred in general pra September, 1927, and December, 1929. Both patie gul babies, born naturally at full time and of healthy mothers, the one a three-para, the other a primipara, neither of whom lost much blood during and after the third stage of labour. The two children began to bleed about thirty hours after birth, in the second case there was hæmatemesis and slight bleeding from the cord-stump as well as melæna. Both were treated within two hours of the appearance of the haemorrhage, both recovered and are now quite healthy. In each instance 10 c.cm. of the mother's blood was injected subcutaneously in the mid-scapular region of the infant's back. In the first case an injection of calcium chloride was made into the buttock also, and 10 minims of 1 in 1,000 adrenaline chloride was given by the mouth, with the hope of its acting as a local styptic, in the second case no other treatment was given except the injection of whole blood, which was performed within the hour after the onset, the child never appeared exsanguinated. Warm, boiled water was given by the mouth, the babies were kept warm, and were moved as little as possible.—I am, etc.,

SIDNEY E. CROSKERY, M.D.

Tunbridge Wells, Aug. 9th.

SIR,—The memorandum of Drs. Boyd and Elliot calls to mind two such cases in my practice during the past twelve months.

The first infant passed fresh blood per anum on the second day, perhaps a teaspoonful in all. This was repeated on two or three successive days, but with the exhibition of sterile water and liquid paraffin for a day or two the condition cleared up. In the second case a 7-para was delivered of a boy easily and without intervention. On the second day a small quantity of blood was vomited. Influenced by the first-mentioned case I treated the child on expectant lines, but with less happy results, for on the morning of the following day a copious haemoptysis occurred, completely saturating the bedding. An hour later the child was extremely pale, pulseless and apparently moribund, so 3 c.cm. of normal horse serum was immediately given intramuscularly into the glutei, and the [illegible] head to foot and placed near the fire.

Colonel JOHN SOUTHEY POSTOCK, C.B.E., late R.A.M.C., Commandant of the Royal Army Medical College, Millbank, died suddenly at The Priory, Burford, Oxon., on August 12th, aged 55. He was born on June 5th, 1875, the eldest son of Dr. E. I. Bostock, whose six sons all served in the war, three of them being killed. John Bostock was educated at Lancing and at Edinburgh University, where he graduated M.B., Ch.B. in 1900. Entering the R.A.M.C. as lieutenant on January 29th, 1901, he became major in 1912, brevet lieutenant-colonel in 1915, and brevet colonel on January 1st, 1918. He served throughout the war of 1914, having accompanied the original Expeditionary Force, and sharing in the retreat from Mons. He was mentioned in dispatches in the *London Gazette* of June 23rd, 1915. At a later date towards the end of the war he was in command of the great war hospital at Eastbourne, and was then Director of Medical Services at the Ministry of Pensions from 1919 to 1923, when he was appointed principal medical officer at Hong-Kong. Six months ago he succeeded Major-General Douglas, V.C., as commandant of the R.A.M.C. College, Millbank. He was awarded the C.B.E. in 1923. In 1909 he married Olivia Emslie, daughter of Mr. Emslie J. Horniman of Chelsea, and had two sons and one daughter. He was throughout his service a most popular officer, alike among his contemporaries and with those who were junior to him. A junior R.A.M.C. officer who had served under him contributes the following appreciation: "John Bostock," for that was how he was known among us all, was a man with exceptional charm. Wherever he went he created an atmosphere of geniality and friendship. Whether as depot commandant in relation to recruit or as senior officer to senior officer, "John Bostock" could always make his personality felt. Almost at the zenith of his career he has been called away. His selection for the post of commandant of the R.A.M.C. College was considered a really happy one; here was the ideal man for the position. He could make the newcomer welcome as no other man could, and could represent the Corps to its distinguished visitors with a natural warmth and elegance. There must be few among his brother officers who do not feel the loss, not only as a really personal one, but also to the Corps as a whole.

Universities and Colleges.

UNIVERSITY OF LONDON.

DR. E. GRAHAM LITTLE, M.P., has been re-elected chairman of the Council for External Students of the University of London for 1930-31.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.

THE undermentioned scholarships have been awarded for 1930:

University Scholarship (£100): H. F. Mossop. Hector Mackenzie Exhibition (£25): J. H. Gosset. Entrance Scholarship in Arts (£50): R. R. McSwiney and I. A. L. Belcher. Entrance Scholarship in Science (£100 and £30): (1) G. W. Hearn; (2) W. F. Hadden and J. L. Lesh. William Tite Scholarship (£25): L. E. Jones.

Medical News.

THE second annual dinner of the Chartered Society of Massage and Medical Gymnastics will be held at the Midland Hotel, Manchester, on Friday, October 3rd, at 7.30 p.m. Further information may be obtained from the secretary of the society, Tavistock House (North), Tavistock Square, London, W.C.1.

NOTICES of the triennial dinner of the Manchester Royal Infirmary Old Residents' Club on October 25th have recently been circulated. Any old residents at the Infirmary who have not received them are asked to communicate with the secretary of the club at the Royal Infirmary, Manchester.

AN introductory course on psychological medicine for the general practitioner will be given at the Tavistock Square Clinic for Functional Nervous Disorders, 51, Tavistock Square, W.C.1, on Wednesday afternoons, beginning on October 1st, and continuing until December 17th. Dr. D. Graham Howe and Dr. H. Crichton Miller will each deliver twelve lectures, and the fee for taking both series is £1 11s. 6d.; the fee for the course can be obtained by application to the honorary lecture secretary at the clinic.

THE Fellowship of Medicine announces that from September 1st to 13th there will be an all-day clinical course at the Queen's Hospital for Children. An all-day revision course at the Westminster Hospital from September 15th to 27th will comprise instruction in all departments of medicine, surgery, and the specialties; visits will be paid to two mental institutions connected with the hospital. There will be a further revision course at the Metropolitan Hospital (especially designed for panel practitioners) from September 29th to October 11th, a course in diseases of the throat, nose, and ear at the Central London Throat, Nose and Ear Hospital from October 6th to November 1st; one in tropical medicine at the Tropical Diseases Hospital from October 7th to 30th; and one in gynaecology at the Chelsea Hospital from October 13th to 25th. Evening courses will also be arranged in that month for the M.R.C.P. and the final Fellowship examinations. Full particulars of the post-graduate work arranged by the Fellowship of Medicine, and the 1931 list of special courses, may be obtained from the secretary, 1, Wimpole Street, W.1.

A POST-GRADUATE course in diseases of the heart and blood vessels will be held from October 13th to 25th, at the Broussais Hospital, 96 Rue Didot, Paris, under the direction of Dr. C. Laubry. Clinical and radiological demonstrations will be arranged as well as formal lectures, and a certificate will be issued at the end of the course. The fee for the course is 1,000 francs. Further information may be obtained from Dr. Y. Meyer at the hospital.

THE German Neurological Society will hold its annual meeting at Dresden on September 18th, when the principal subject for discussion will be the theory and practice of the problem of resistance in nervous diseases, introduced by Drs. Boeke of Utrecht, Spatz of Munich, Foerster of Breslau, and Goldstein of Berlin.

IT is announced that the fourth Congress of the World League for Sexual Reform on a Scientific Basis has been postponed for three days, and will now be held in Vienna from September 16th to 23rd. The subjects for discussion include: sexual difficulties of the young, of adults, and of mentally abnormal persons; the internal secretions, the relation of sexual abnormalities to the administration of justice; birth control; and the rights of children. Further information may be obtained from the secretary of the congress at the Congress Bureau, Postfach 63, Vienna I/15.

THE second Congress of the Federation of the Latin Medical Press will be held at Brussels from September 28th to 30th in connexion with the centenary celebration of Belgian independence. Topics of discussion include the medical journal and contemporary medical journalism, the rights of editors, the production of a dictionary of medical terms, and the part played by the medical press in diffusing important scientific and professional views. Further information may be obtained from Dr. R. Beckers, general secretary of the conference, 36, Rue Archimède, Brussels.

THE thirty-ninth French Congress of Surgery will be held in Paris under the presidency of Dr. Maurice Arnray, surgeon to the Hôpital Lariboisière, from October 8th to 11th, when the following subjects will be discussed: [illegible] arthritis, introduced by Pierre Brocq of Paris and [illegible] traumatic spondylitis (Kümmel-Verneuil disease), introduced by Frœlich of Nancy and Albert Mouchet of Paris; and preparation of patients for operation, introduced by Lenormant of Lille and Sauvé of Paris. Further information can be obtained from the general secretary, Rue de [illegible] 12, Paris, VIe.

AN address entitled "Diet and dental disease: What we have learned from animal experiments" delivered by Mrs. Edward Mellanby as the Fourth [illegible] on Paget Memorial Lecture to the Research [illegible] on June 3rd, is published [illegible] (reported in the *British Medical Journal* of June 14th (p. 1101).

THE sixth annual report of the National Institute for the Deaf, which was presented to the annual meeting of the society last May, has now been printed, and may be obtained from the offices of the institute, 2, Bloomsbury Street, W.C.1. A reference to the annual meeting appeared in our columns on June 7th (p. 1070).

DR. THEODOR AXENFELD, professor of ophthalmology at Freiburg, and Hofrat Ernst Fuchs, professor of ophthalmology at Vienna, have been elected honorary members of the Japanese Ophthalmological Society.

THE following appointments have recently been made in French faculties of medicine: M. Maillard, professor of biological and medical chemistry; M. Wunschendorff, professor of pharmacological chemistry and toxicology at Algiers; and M. Leulier, professor of pharmacy and pharmacology at Lille.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

175. Electrocardiographic Changes in Quiescent Rheumatic Heart Disease.

M. J. SHAPIRO (*Amer. Heart Journ.*, April, 1930, p. 504) summarizes the electrocardiographic changes that have been found in acute rheumatic fever. These are: (1) prolongation of the P R interval (in 87 per cent. of cases); (2) alterations in the Q R S deflection, the R T interval, and the T-wave; and (3) irregularities of rhythm. In the present investigation electrocardiographic tracings were taken from 119 children with definite histories of rheumatic infection; 73 of these children had definite rheumatic heart disease. The P-wave was notched in 4 per cent. and unduly large in 4 per cent. In 8 per cent. the P R interval was prolonged to 0.2 second or more. Notching at the peak of the Q R S deflection in Lead I or II, or both, was found in 3 per cent., and this complex was widened in the same number. Absence or abnormality of the isoelectric period was present in 63 per cent. of the patients; in a few of these the T-wave started as a direct continuation of the interrupted R-wave, suggesting the change commonly seen in coronary occlusion. In three instances the T-wave was negative in Lead I or II, or both. Auricular and ventricular extrasystoles were rare. A control group of 50 children with normal hearts showed no changes in the P R interval or Q R S complex, nor were any other significant variations observed. Repeated tracings taken over a period of a year in a group of 20 rheumatic children were contrasted with those obtained by repeated examination of 10 normal children. In the latter group the tracings remained unchanged, while among the rheumatic group alterations took place from time to time in the P-wave, the Q R S deflection, the T wave, and the R T or S T interval. The author concludes that the electrocardiographic changes present in children suffering from quiescent rheumatic heart disease are similar to those present in acute rheumatic fever, but the frequency is less in the quiescent group.

176. Prolonged Form of Meningococcal Sepsis.

I. LUNDHOLM and R. STROMAN (*Acta Pediatrica*, May 20th, 1930, p. 518) describe a case, in a 12-months old girl, of protracted remittent fever without ague or general symptoms, but with intermittent eruptions over the extremities and the trunk of pink papules or nodules; these were fairly evenly rounded, uniform in size, and non-confluent, some having small petechiae in the centre. There was no loss of consciousness, no stiffness of the neck, no symptoms of meningitis, and, on lumbar puncture, the cerebro-spinal fluid was clear and not under tension. A blood culture yielded Gram-negative diplococci which, morphologically and biologically, were typical meningococci. The authors remark that the prognosis is usually favourable in these cases, but it should be guarded, since meningitis, which is usually fatal, may not appear until after the lapse of several months, and also because there may be a recrudescence of the disease after even a two weeks' remission. An intramuscular injection of 20 c.cm. of antimeningococcal serum was given, and three weeks later a further 1 c.cm. was injected subcutaneously, but this caused a marked urticaria and menacing general symptoms, so its use was discontinued. A colloid gold salt was administered for three days; there followed unusually marked remissions of fever, and new recrudescences of the exanthem for three days. On the fourth day the patient developed a sore throat, which passed off after three days, whereupon she was free from symptoms of meningococcaemia. This termination is not attributed to the therapy, but is stated to be in some measure characteristic of the disease.

177. Raynaud's Disease and Arsenic Retention.

A. F. KRAETZER (*Journ. Amer. Med. Assoc.*, April 5th, 1930, p. 1035) calls attention to recent work by Throne and Myers on arsenic retention and eczema, and mentions many unsuspected or little known sources of arsenic; among them are woollen and cotton fabrics, silk impregnated with tin, tobacco, and some common medicaments such as rhubarb and soda, sulphur, and calamine and zinc lotions. He records the case of a woman, aged 38, who had worked for fourteen years in a greenhouse where insecticide sprays containing arsenic were in daily use. After attacks each spring of pruritic rashes on the hands with frequent soreness of the throat, chronic constipation, and general poor health, she began to exhibit signs of Raynaud's disease in the fingers and toes, which caused great pain and inconvenience. The attacks were almost invariably brought on by motoring in cold weather. Physical examination of the patient showed signs of arsenic retention, and thirty-six hours after the intravenous injection of 1 gram of sodium thiosulphate the urine was found by the Marsh test to contain 0.062 mg. of arsenic per 100 grams of dried material. A five weeks' course of bi-weekly injections of 1 gram of sodium thiosulphate was given, after which the dose was continued once a week. At the same time the patient was placed on a low carbohydrate diet, with enemas of sulphonated bitumen, and quarter-gram doses of thyroid extract twice a day. Diminution of the severity of the trouble was soon noticed and was steadily maintained. The toes soon cleared up; the agony during the recovery stage after putting the hands in warm water became less acute and then disappeared. The congestion stage shortened and then vanished, so that at the end of two months she was free from attack, even after driving her car in cold, wintry weather.

178. Encephalitis following Varicella.

S. GRAHAM (*Arch. Dis. Child.*, April, 1930, p. 146) records two cases in boys, aged 3 and 6 respectively, in whom a mild attack of varicella was followed by encephalitis. The most prominent feature of each case was a pronounced degree of ataxia, but neither showed any paralysis. In each case lumbar puncture gave issue to a clear colourless fluid under slight hypertension, and containing an increased number of leucocytes. Both patients made a complete recovery. Like all the other examples of varicella encephalitis on record.

179. Syphilis Contracted during Post mortem Examination.

M. KITCHEVATZ (*Bull. de Derm. et Syph.*, April, 1930, p. 424) reports the case of a young medical student who pricked his finger while making a post mortem examination of a child who had died from congenital syphilis. He painted the wound with iodine and washed it well in soap and water, but about a fortnight later he noticed a small red nodule; this was opened and sero-sanguinolent fluid was evacuated. The lesion was treated as a whitlow, and no suspicion of syphilis was entertained. The swelling was painless, but later on the glands at the elbow and axilla enlarged, and the hand became swollen; it was then thought to be tuberculous. A dermatologist subsequently diagnosed a chancre, and further examination provided ample evidence of syphilis.

Surgery.

180. Spasmodic Torticollis.

C. H. FRAZIER (*Annals of Surgery*, June, 1930, p. 849) describes four cases of spasmodic torticollis treated successfully by operation. The muscles concerned in the movements of spasmodic torticollis are the sterno-mastoid, which rotates the head toward the opposite side while tilting it toward the homolateral side; the upper portion of the trapezius, which causes homolateral rotation and homolateral retraction while pulling the shoulder upward; and the splenius capitis and the splenius cervicis, which with the semispinalis capitis and the longissimus capitis cause homolateral tilting and contralateral rotation. The most powerful rotators are the rectus capitis posticus major and minor, and the obliquus capitis inferior. Before the operation the muscles at fault must be identified: usually the sternocleidomastoid is affected on one side and the posterior group on the other. In all severe cases of the spastic torticollis in which a focal organic lesion of the neostriatum is at fault operation is the only means to give relief. The operation must include severance of the spinal accessory nerve, and the first three cervical roots must be rendered functionless in the four cases reported the roots on both sides were included. They were crushed with an artery clamp or a ligature of arterial silk after which the spinal accessory nerve was exposed by retraction of the cord by gentle traction on a dentate ligament. In the operation for the relief of spasmodic torticollis [illegible] of choice and not of necessity it must be covered [illegible] was the operation undertaken in these four cases in which convalescence was uninterrupted.

contained 2 c.cm. of extract. Starting with one ampoule, and rapidly increasing to six given in one dose daily, the condition of the patient improved, and after six days had gained 3 kilos in weight, and showed an increased red cell count of 900,000 per c.mm. and a gain of 15 per cent. in haemoglobin. After this initial improvement, in spite of the great amelioration of the general symptoms, the condition of the blood remained stationary. It was now found that raw liver could be taken well without causing vomiting or diarrhoea; the injections were therefore stopped and the liver diet was restarted. Marked improvement resulted, and about two weeks later the red cell count was 4,360,000 and the haemoglobin percentage 75.

Anaesthetics.

188. Sodium Amytal as a General Anaesthetic.

A. I. LUDLOW (*China Med. Journ.*, April, 1930, p. 348) records a series of eight cases in which he has used sodium amytal (the sodium salt of iso-amyl-ethyl-barbituric acid) as a general anaesthetic in adults in Korea for operations in various parts of the body. Intravenous injections were used and induction was simple; the rate of administration did not exceed 1 c.cm. a minute, and the patient was deeply asleep in three to five minutes. There was usually some resistance at the skin incision, on rough handling of the peritoneum, and in a case of anal fistula, but no unpleasant sensations were reported on the return to consciousness. In these cases chloroform (or ether) had to be called upon for a time, but in two cases—one a dissection of the axilla, the other an operation upon the sterno-mastoid—no other anaesthetic was used. Anaesthesia was helped by a preliminary dose of morphine, and by the administration of the amytal in two portions, separated by a few minutes. A 10 per cent. solution was used, and about 15 to 20 mg. for each kilogram of body weight was found to be the quantity of the drug required. Except in the case of one alcoholic patient there was no post-operative trouble, though one or two patients became restless; discomfort, nausea, vomiting, and bronchial irritation were all absent. The patients slept for from three to twelve hours after the operation.

189. Local Anaesthesia in Minor Gynaecological Operations.

H. GAUDIER (*Bull. Soc. d'Obstét. et de Gynécol.*, April, 1930, p. 253) comments on Ceytlin's method of local uterine anaesthesia, which consists essentially in the interruption of the uterine nerve supply at a point where it is most easily accessible and the nerves are grouped in a minimal space—namely, at the convergence of the ramifications to the plexus of Frankenhauser; this point is situated below and a little behind the crossing of the ureter and uterine artery. Thus it is a parametro-ganglionic anaesthesia by an infiltration of the cervical tissues, differing from other forms of local anaesthesia. The following is the technique employed. The cervix is seized and drawn down with forceps, lateral traction being made to expose the lateral cervical region. At the insertion of the vaginal mucosa on the cervix a needle is inserted, parallel to the cervix, to a depth of 2 cm.; the fact that it has not entered a vein should be verified by aspiration, and then 10 c.cm. of a 1 per cent. adrenalinized solution of allocaine is slowly injected. The opposite side is similarly treated. Uterine anaesthesia is complete in five to eight minutes; it lasts on an average for half an hour, and under it such operations as dilatation of the cervix and curetting are painless. Djellert reports no ill effects after this anaesthesia in 205 operations. The special indications for its use are dilatation of the cervix, curettage, and intentional abortion; contraindications are the general ones of minor gynaecological interventions, such as infections of the parametrium and the adnexa. The advantages of this method, besides its simplicity, are: it does not modify the elasticity of the cervical tissues in conserving the facility of uterine contractions; it is haemostatic to a certain degree; and it does not cause shock.

190. Avertin Anaesthesia.

S. M. VASSALLO and T. A. JERMY (*Kenya and East African Med. Journ.*, April, 1930, p. 12) point out that the administration of an anaesthetic in the Tropics often presents difficulties, both as regards the anaesthetist and the patient. Although the use of a local anaesthetic possesses great advantages, it is usually unsuitable for native cases, since the patients are often terrified by the appearance of the surgeon and the steps of the operation. It seemed to the authors that the new anaesthetic, avertin, might obviate some of these difficulties. Avertin (tribromethylalcohol) is obtainable in solid or liquid form, 1 c.cm. of the latter being the equivalent of 1 gram of the former. Solid avertin is a white crystalline powder which sublimates easily, has a melting point of 80° C., and at 37° C. dissolves in water to a concentration of 3 per cent. At a higher temperature dibromacetylaldehyde is produced, and since this is extremely irritating to the intestinal mucous membrane even in small quantities, the temperature of 37° C. should not be exceeded in the preparation of the solution, which is freshly prepared for each case: it should be kept tightly corked, since it crystallizes very readily on exposure to the air. The dose required for anaesthesia varies from 0.1 to 0.15 c.cm. per kilo of body weight; the authors have found that a dose of 0.12 c.cm. induces the best anaesthesia. The addition of 100 c.cm. of milk to the water employed as a solvent appears to induce a slower and deeper anaesthesia. The solution is introduced slowly into the rectum, the process taking about four minutes; the end of the tube is kept in place until deep sleep occurs, when the fluid remaining in the rectal ampulla is drained off. The patient lies on his side throughout the induction. Anaesthesia follows within eighteen minutes of the beginning of the induction. The respiration is the only sure indication; when anaesthesia is complete the breathing is moderately shallow, absolutely regular, and mechanical. Avertin produces a slight fall in the blood pressure; in fatal cases the respiration ceases before the circulation. The authors remark that this method of anaesthesia causes no shock; it has been employed by them in thirty cases with favourable results. Only one fatality occurred, but as no post-mortem examination was allowed the cause of death is unknown. The after-effects seem to be unimportant. The authors consider the chief indications for this anaesthetic procedure are long operations which are likely to be accompanied by shock, and operations where the patient presents derangements which make general anaesthesia undesirable.

Obstetrics and Gynaecology.

191. End-results in Cancer of the Cervix.

REPORTING results of treating carcinoma of the female genital organs during 1913–24 at Stuttgart, P. FELDWEG (*Zentralbl. f. Gynäk.*, March 29th, 1930, p. 779) states that it was possible to trace the fate after at least five years in 723 cases, in 23 per cent. of which the cure had persisted for five years. Of the 405 cases treated from 1918 to 1924, 26.4 per cent. showed no recurrence. Cervical carcinoma, during 1918–24, gave 23.8 per cent. of cures in 281 cases, of which 161 were operable, 103 inoperable, and 12 "terminal" on admission. During eleven years 92 Wertheim operations for cervical carcinoma were attended with a primary mortality of 8.7 per cent., and 38 per cent. of five-year cures; adjuvant radiotherapeutic measures were used in about half these cases. During the same period 374 cases of cancer of the cervix were treated by radiotherapy only, with 16.8 per cent. of cures. Of the 176 operable cases within this group, 28.4 per cent. were cured [illegible] during the period 1918–24 the cures among [illegible] treated reached 34.7 per cent. It is stated [illegible] two years radical operation for cervical cancer [illegible] abandoned.

192. Suppurative Puerperal Thrombophlebitis

LEQUEUX (*La Vie Méd.*, April 26th, 1930, p. [illegible]) points out the importance of distinguishing between [illegible] caemia and suppurative puerperal [illegible] of the pelvic veins: the former yields only to [illegible] while the latter is amenable to [illegible] (venous ligature). In suppurative [illegible] the clinical course is generally [illegible] febrile puerperium, in which no cause [illegible] been recognized, a rigor occurs from the fourth to the [illegible] day and ushers in an abrupt elevation of temperature which as a rule soon falls to the normal. At intervals of a few hours or days the rigor and high pyrexia recur, and the patient's condition gradually becomes worse, local signs being absent or insignificant; blood cultures are almost invariably negative. The diagnosis of suppurative pelvic thrombophlebitis is clinched by the sudden appearance of a thoracic syndrome—dyspnoea, cough, and pain in the chest—due to a septic embolus. Death of the patient follows from pulmonary abscess or abscesses, or from purulent pleurisy, the results of the first or of succeeding emboli. Simple thrombophlebitis also is characterized by pyrexia, rigors and [illegible] pulmonary symptoms; but apyrexial intervals are frequent, rigors are less intense, and pulmonary embolisms, if septic, are dangerous only by their mechanical consequences. Suppurative thrombophlebitis is a local [illegible] the danger of which lies in its septic and multiple pulmonary metastases; in the majority of cases it is lethal. Puerperal pyaemia is a

different form of infection, resulting directly from septic endocarditis, which may be produced by bacteraemia, or by attachment to the endocardium of a septic embolus from the pelvis. Lequeux states that of late years necropsies in puerperal sepsis have shown a 20 to 50 per cent. incidence of pelvic thrombophlebitis, intravenous suppuration, however, not being always noted.

193. Radical Treatment of Incomplete Abortion.

A. G. SCHULZE (*Minnesota Med.*, May, 1930, p. 310) discusses the treatment of incomplete abortion, and records a series of 235 consecutive cases treated by instrumental curetting in which no death occurred. He finds that it is advisable that the patient should have been afebrile for five days before any operation is performed. An examination is then made under anaesthesia, 1 c.cm. of pituitrin is administered, and the os is dilated if necessary. After the curetting a pack of plain dry gauze is inserted; this is immediately removed, and is replaced by a strip of gauze soaked in 3 per cent. iodine. This strip is also removed, another strip of iodine gauze being then inserted and left in for twenty-four hours. The author considers this method safer than conservative treatment or digital curetting. Perforation of the uterus never occurred in the series, and uterine muscle was only once reported as being present in the curettings. The average stay of the patients in hospital was five days before the operation, and seven days afterwards.

194 Fibroma of the Ovary.

ACCORDING to M. VITALI (*Ann. Ostet. e Ginecol.*, April, 1930, p. 364) fibromas constitute about 2 per cent. of ovarian tumours, and are rarely associated with pain or with abnormalities of menstruation. At the operation about one in five is found to be twisted to an extent not usually exceeding 90 degrees about a pedicle which commonly consists of the utero-ovarian and ovaro-pelvic ligaments, but may include the Fallopian tube. Not infrequently at operation an ovarian fibroma is found which, although having undergone one or more complete torsions, has caused no acute symptoms. In other cases torsion is associated with severe pain, which may become worse (leading to an operation of urgency), pass away, or recur. Rupture of the pedicle and gangrene of the fibroma may follow, but as a rule the consequences of torsion are less serious in fibroma than in an ovarian cyst. A case is described in which after rupture of a left tubal pregnancy the operation revealed also on the other side an ovarian fibroma, twisted through 720 degrees, and causing tubal torsion; the ovary and tube had contracted many adhesions, but no morbid symptoms had directly resulted.

195. Pregnancy and Dentition.

W. LINTZ (*Med. Journ. and Record*, May 7th, 1930, p. 452) reports an investigation of a series of pregnant and non-pregnant women with regard to the influence of this condition on the teeth. He finds that the upper teeth are lost first, and that the figure for missing teeth was 44 per cent. in pregnant women, as compared with 17 per cent. in the non-pregnant. He concludes that a woman loses an average of two teeth for each pregnancy, and that the remaining dental apparatus in the non-pregnant is in a much better condition than in the pregnant. The molars are the first teeth to disappear, and the canines the last. The critical age for loss of teeth is said to be 40, after which there is a decided increase in the loss for each year.

Pathology.

196. Experimental Syphilis in the Guinea-pig.

TANI, M. KAKISHITA, and K. SAITO (*Zentralb. f. Bakt.*, June 1d, 1930, p. 73) find that guinea-pigs inoculated intra-esticularly with suspensions of syphilitic rabbit's testicle do not contract syphilis. If, however, the inoculation is made intracutaneously into the scrotum, about 55 per cent. o. the animals show chancres. The incubation period may last from one to six weeks, but is generally about seventeen prostand the lesions persist as a rule for about a fortnight. tate to express' that in these rabbits swellings sometimes agent from the glandu[illegible]eal fold; examination of the fluid hypertrophy and urinary[illegible]arification revealed the presence beginning of obstructive[illegible]gically indistinguishable from *Trep.* oedematous prostates 5 were therefore made to determine prostatic massage oculation into the perineal fold would Before a course oopment of syphilis. It was found that should be taken to oxic rabbit's testicle uniformly gave rise tion of the vesical neck, tion. The inoculation was made of the prostate. inner raw part of the perineal fold, which appears when the scrotal sac is drawn outwards with the fingers. After an incubation period of about eleven days a swelling appeared; this spread over the whole inner surface of the inoculated side, and later on to the opposite side. It lasted as a rule for about seven weeks. By scarifying the lesion and inoculating the juice into the perineal fold of a fresh guinea-pig, it was possible to reproduce the disease in at least six successive animals. Inoculation by this route with rabbit material was uniformly successful, and it would therefore appear to be more satisfactory than scrotal inoculation. This route was likewise found to be suitable for the direct inoculation of human syphilitic material.

197. Anaemia in Jaundice.

F. M. JORDAN and C. S. MCVICAR (*Amer. Journ. Med. Sci.*, May, 1930, p. 654) have tried to explain the etiology of anaemia which occurs in jaundiced patients, 347 cases of which have been studied. Anaemia was regarded as present if the haemoglobin percentage was below 70, and the red cell count under 4 million per c.mm. Anaemia was found in 108 cases, of which 33 were associated with carcinoma, 31 with intrahepatic jaundice, 30 with cholelithiasis, and 14 with stricture. In this series of cases the intensity of the anaemia was apparently independent of either the intensity or the duration of the jaundice. It is concluded that relatively severe secondary anaemia may occur in cases of jaundice due to any cause and independently of infection or loss of blood. It is suggested that nutritional factors are of great significance in the etiology of anaemia occurring in jaundiced patients; it has been shown that in dogs the amount of regeneration of haemoglobin can be controlled by varying the diet; it was found that in animals given the basal diet ligation of the common bile duct inhibited regeneration of haemoglobin, whereas animals fed on liver diet were more resistant to this effect of obstruction. It was also shown that the degree of jaundice, measured by the serum bilirubin figure, varied with the degree of haemopoietic stimulation and the consequent activity of the metabolism of pigment, rather than with the total amount of circulating haemoglobin.

198. Carbohydrate Metabolism in Diphtheria Intoxication.

F. F. SCHWENTKER and W. W. NOEL (*Bull. Johns Hopkins Hosp.*, April, 1930, p. 259), who injected rabbits with diphtheria toxin and made clinical observations on diphtheria patients, come to the conclusion that there is a marked abnormality in the carbohydrate metabolism in diphtheria intoxication. This is manifested by a primary increase in glycogenolysis in the first stage of the toxaemia and a resultant rise in blood sugar. Subsequently a marked hypoglycaemia ensues in very severe cases. In the more protracted cases, however, a decrease in glycogenesis follows; this is probably due to a suppression of the production of insulin with a resultant hyperglycaemia. The liver and muscles show a pronounced diminution in glycogen in all cases. The authors therefore maintain that the symptoms of diphtheria intoxication are in large part due to secondary nutritional disturbances in all the essential body tissues. The administration of insulin in these cases causes assimilation of the dextrose, most probably through the usual glycogenic channels.

199. The Calcifying Action of Irradiated Ergosterol.

PFANNENSTIEL demonstrated the remarkable calcifying property of irradiated ergosterol when given in large, almost subtoxic, doses, and this has led to a study of the action of this substance on the evolution of tuberculous lesions. Levaditi, Li Yuan Po, and Spiess have recently published the results of their experiments on rabbits, and A. POLICARD, PAUPERT-RAVAULT, and P. BARRAL (*C. R. Soc. de Biologie*, June 20th, 1930, p. 633) now report the results of similar experiments on guinea-pigs. The animals were inoculated with the same strain of *B. tuberculosis*, and were given varying doses of ergosterol in the form of vigantol or sterogyl, which were administered both immediately after the inoculation and after the lapse of some time. It was found that the irradiated ergosterol caused, but only in large doses, an accumulation in the tuberculous lesions of fixed mineral matter, composed mostly of calcium salts. The calcification was produced particularly in the caseous areas, and only by employing such doses as would cause calcareous deposits in normal organs. The present authors conclude that this action of irradiated ergosterol has a certain importance, and that some day the calcification of pulmonary, ganglionic, and osseous tuberculous lesions may be considered. They agree with the previously mentioned investigators that the employment of such an active substance necessitates great prudence. The cachexia, loss of weight, and the heterotopic calcifications it produces emphasize the scrupulous care necessary in its therapeutic use in large doses.

SANDOZ

SANDOZ

CALCIUM-SANDOZ

$(C_6H_{11}O_7)_2$ Ca.

Unique Advantages:

1.—It is effective. It supplies the physiologically active calcium ion.

2.—It shows distinct superiority in all modes of administration.

ORALLY: It is well absorbed. It is easily administered and does not upset the digestive tract.

INTRAVENOUSLY: It is better tolerated than calcium chloride. The acid-base factor is eliminated.

INTRAMUSCULARLY: It is painless and non-irritating. It is the only calcium salt which can be so administered in adequate doses.

3.—It enables physicians to adequately meet the requirements of any given case.

BY VEIN, for acute need.
BY MUSCLE, to secure intense and prolonged action.
BY MOUTH, for prolonged administration, to meet an increased demand by the organism.

4.—It is completely sufficient in itself as a therapeutic agent.

CALCIUM-SANDOZ is supplied in

Ampoules containing a 10% sterile solution for intravenous or intramuscular injection.
5 c.c. size: Boxes of 2 and 10 ampoules.
10 c.c. size: Boxes of 1, 5, and 20 ampoules.

Powder for oral administration.—Cartons of 2, 4, and 16 ounces.

Tablets for oral administration.—Each tablet contains 25 grains of calcium gluconate and is especially adapted for division into three parts. Boxes of 30 and 150 tablets. Cartons containing 12 boxes of 30 tablets.

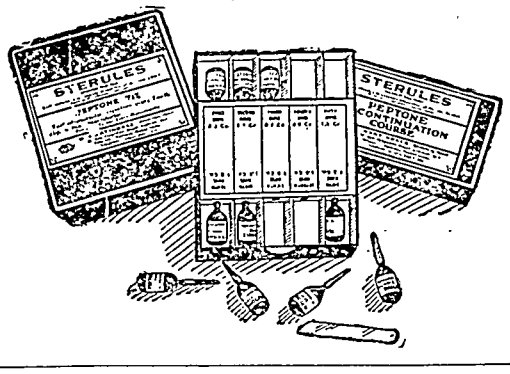
DOCTOR'S CHINA TEA

WHY IT IS PRESCRIBED FOR GASTRIC PATIENTS



When ordinary tea is out of the question it is essential that only the finest China should be drunk. Doctor's China Tea has won the enthusiastic approval of practitioners simply because it is a perfect blend of the finest China leaf with all excess tannin eliminated. It can therefore be prescribed for invalids and dyspeptics with safety—it has no ill after-effects.

Priced at 3/- and 3/8 per lb. A super quality at 4/2 per lb.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombieres treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

August 16th, 1930.

County Council of Durham

ASSISTANT WELFARE MEDICAL OFFICER

The County Health Committee invite applications for the appointment of an Assistant Welfare Medical Officer (woman) at a commencing salary of £600 per annum, rising by annual increments of £25 to £700 per annum. Travelling expenses will be paid by the County Council according to scale.

The appointment will be held subject to three months' notice on either side and to the following conditions:

(1) The officer appointed must be a registered Medical Practitioner between the ages of 25 and 45 years, must devote the whole of her time to the duties of the office and must not engage in private practice.
(2) She should either have held a previous appointment as Medical Officer of an Ante-natal Clinic with the approval of the Minister of Health or have had at least three years' experience in the practice of the profession and special experience of practical midwifery and ante-natal work. The holding of a Diploma in Public Health and practical experience in bacteriological laboratory work will be deemed additional qualifications for the post.
(3) She will be subject to the directions of the County Medical Officer.
(4) She will be required to reside in Durham City or such other place as required by the Council.
(5) She must be prepared, if called upon, to act as Locum Tenens to other Members of the Medical Staff of the County Medical Officer.
(6) The appointment will terminate on marriage.
(7) The candidate appointed will be required to pass the County Council's medical examination and will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

Applications, endorsed "Assistant Welfare Medical Officer," with copies of not more than three recent testimonials, must be forwarded on or before 30th instant to the County Medical Officer, Shire Hall, Durham, from whom forms of application can be obtained.

Shire Hall, Durham. HAROLD JEVONS, Clerk of the County Council.
August 11th, 1930

County Borough of Darlington.

HEALTH VISITOR

The Corporation invite applications for the appointment of Health Visitor.

Applicants must hold the following qualifications:

(a) the new Health Visitor's Certificate of the Royal Sanitary Institute, or
(b) the Certificate for Health Visitors prescribed by the Board of Education Regulations of 1919, or
(c) have held a post as Health Visitor approved by the Ministry of Health.

The duties are chiefly concerned with maternity and child welfare, and the successful applicant will be required to carry out such duties under the direction of the Medical Officer of Health.

The salary for the appointment (under the Corporation's scale) as at present adjusted by reference to the rise or fall in the cost of living is £172 16s., and is subject to such other conditions of such scale as are applicable, and additional allowances amounting to £11 in respect of travelling and uniform are made.

The salary is subject to a deduction of 5 per cent. under the Local Government and Other Officers Superannuation Act, 1922, and the successful applicant will be required to pass a medical examination.

Applications, stating age, qualifications, and experience, must reach the Medical Officer of Health, Feetham, Darlington, not later than Monday, September 1st.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(FOUNDED 1880.)

12, Stratford Place,
Oxford Street, W.1.

Tele. Address: Triform, Wesdo—London.

Telephone: Mayfair {1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

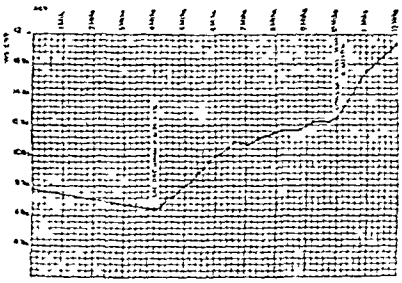
IN VITAMIN "D"

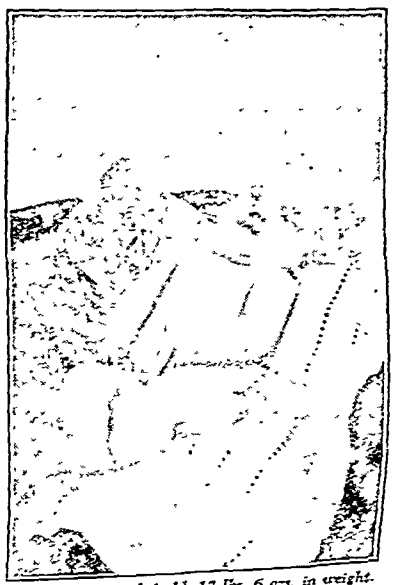
A "RESURRECTION"

.....GUILDFORD
30 6 30



"Baby Hook, came under my care shortly after birth suffering with marasmus following whooping cough. Broncho-pneumonia developed and was with great difficulty cleared up, leaving the child in a very low condition. Feeding proved a difficult problem, several things were tried without beneficial results. The results with Cow & Gate were truly wonderful, indeed it is a case of 'a resurrection.'"

(Signed).....M.B.Ch.B.



Lacidac (separated) and Brestol, the Cow & Gate Humanised Cream, were used in the early days of treatment. Cow & Gate Full Cream and Brestol being used subsequently.

BEFORE—4 months' old, 6 lbs. 9 ozs. in weight.

Progress Chart

AFTER—10 months' old, 12 lbs. 6 ozs. in weight.

June 1930. Baby Hook has now won a prize in a Baby Competition!

Write for literature and clinical samples of Lacidac and Brestol.

Students of Medicine

FOR the guidance and assistance of those wishing to enter the Medical Profession and for those already qualified who are desirous of planning a career there will be published, on

September 6th,

a

Special Educational Number

of the

British Medical Journal

THIS Number will contain full information regarding Medical Education and the fees charged by the teaching and examining bodies in England, Scotland, and Ireland. Details of the various Services and branches of specialist practice will also be included. The enlarged Advertisement Sections will contain much that is of value to the Student and Practitioner, and will certainly repay careful examination.

The Educational Number replaces the ordinary issue of the B.M.J. for September 6th, and the price is, as usual, 1s. 3d.

DEMONSTRATIONS OF PHYSICAL SIGNS IN CLINICAL SURGERY

By HAMILTON BAILEY, F.R.C.S.(Eng.),
Surgeon, Dudley Road Hospital, Birmingham.

The illustrations have been still further improved and increased in number for this edition.

LANCET.—"This excellent book has been enlarged. Many new pictures have been added, and they are of the high standard of the rest. Mr. Bailey must be congratulated on the production of a work which gives just that assistance which is needed by the medical student attending his first clinics. It has won deserved popularity, and we predict for it a long and successful life."

BRIT. JOUR. SURG.—"An admirable book which we can recommend to all students."

Greater Comfort for your Patients.

"The Rose Corset-Belt"

which has set a new standard and proved so effectual in all abdominal cases where support is required. The X-rays have shown the actual uplift.

Each Corset-Belt is cut and fitted to individual requirements, and the patient is kept under observation until every satisfaction is given to both patient and doctor.

I have also invented an improved Colotomy Belt for both male and female patients.

My work is recommended by eminent members of the medical profession, and the following hospitals: St. Bartholomew's Hospital, Metropolitan, Charing Cross, Middlesex, London Temperance.

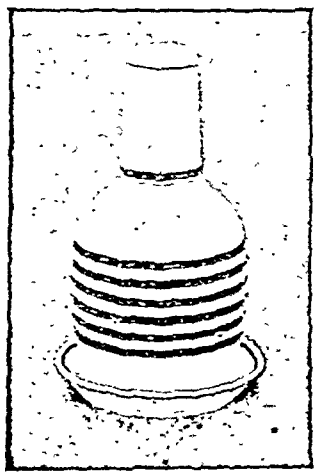
ONLY BREAKAGE CAN DESTROY ITS HEALTH VALUE

Only by breakage can you destroy the value of "Vita" Glass as a permanent inlet for the ultra-violet rays.

One of the most interesting tests ever made in proof of this permanency is being carried out by the Building Research Station, and an interim report states:—"The behaviour of 'Vita' Glass in sunshine cannot be deduced from artificial solarisation without serious risk of error." "Vita" Glass exposed to artificial radiation regains its solarised level of transmission on subsequent exposure to natural daylight, after which continued exposure to sunlight causes no further change.

Those interested in "Vita" Glass for their own use or for use in buildings under their control are invited to write for full particulars to the "Vita" Glass Marketing Board, 9 Crown Glass Works, St. Helens, Lancashire.



"Vita" Glass is obtainable from local Glass Merchants, Plumbers, Glaziers and Builders.

"VITA" GLASS

"Vita" is the registered Trade Mark of Pilkington Brothers Limited, St. Helens

V-327

Extract from The Lancet, August 2, 1930:

12½" High and 7½" wide. Total contents one quart. Summary of reports: 1. The steriliser is capable of killing off pathogenic bacteria as found in drinking water in very high concentration. 2. The treated water has itself bactericidal properties

The Catadyn Steriliser treats up to 250,000 gallons of water without renewal.

STERILISING WATER BY THE CATADYN METHOD OF KRAUSE.

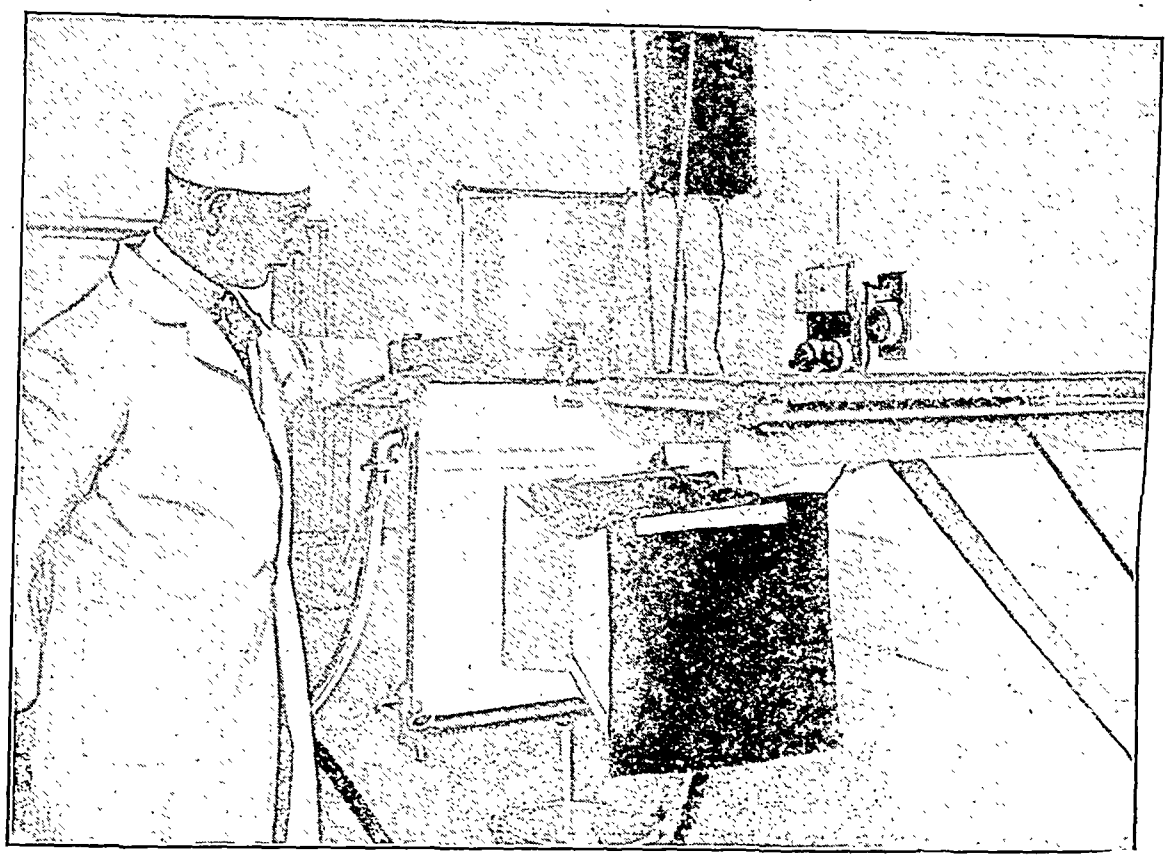
About 50 years ago the Swiss biologist, Carl v. Nägeli, made the observation that micro-organisms died in water which was kept for several weeks on end in vessels of silver or copper. He could offer no explanation of this effect, as he was unable to detect the presence of any metal in solution and his experiments precluded the possibility of the germs having been killed by radiation. He called the phenomenon "Oligodynamics," and after his death Dr. G. A. Krause, Munich, a physicist, and others, confirmed and extended his observations. The catalytic-dynamic properties of finely divided silver have been utilised in the "catadyn" method of sterilising water. The effect of minute quantities of the spongy metal distributed over porcelain rings, beads, or particles of sand on the living organisms in water has been accurately measured; in most instances the colon bacillus has been taken as the test organism. It is claimed that the filtrate also in some mysterious way acquires and retains the germicidal power originating in the materials of the catadyn process. Severe and prolonged critical tests have been applied and the evidence advanced is remarkably convincing. Before it can be applied on a commercial scale the question of expense of materials and containing vessels will require scrutiny, but a prima facie case has been made out for the consideration of the physicist, the biologist, and the public health expert.

CATADYN

Steriliser

Catalytic and Dynamic Action

The British Catadyn Company take this opportunity of informing the Medical Profession that the simple form of Catadyn Steriliser illustrated here is now available for general use.



It is important to note that the colour, taste and smell of Catadyn treated water is unaffected. Any normally infected water will be sterilised by about half an hour's contact.

All enquiries regarding this new method of sterilisation, which will be dealt with individually, should be sent to the address below.

MICKLEFIELD IRRADIATED MILK

TREATING THE MILK

By this Process—

(1) VITAMIN A AND NATURAL FLAVOUR ARE PRESERVED.
(2) VITAMIN D CONTENT IS INCREASED 1,800 PER CENT., OR TEN TIMES THAT OF ANY OTHER IRRADIATED MILK.

One pint equivalent in Vitamin D to 600 drops or 12 grammes of average Cod-Liver Oil.

A ten weeks' test recently conducted at the Infants' School, Rickmansworth, under the supervision of the Medical Officer of Health, gave the following results:—

(1) 16 children (controls) had their usual ordinary milk.
(2) 29 ,, 1/3-pint of Grade A (T.T.) milk five days a week.
(3) 30 ,, ,, Micklefield ,, ,, ,,

(1) Average increase in height .605-in. (2) Average increase in weight 9.72 ozs. more than (1).
(2) ,, ,, ,, .610-in. (3) ,, ,, ,, 10.9 ozs. more than (1).
(3) ,, ,, ,, .744-in.

Full particulars appeared in an article in the LANCET, January 18, 1930, p. 127, et seq., a reprint of which will be sent post free on request.

The milk is delivered every week-day in London; elsewhere by arrangement.

FOR INTERNAL TREATMENT OF
GONORRHŒA, URETHRITIS AND OTHER AFFECTIONS OF THE GENITO-URINARY TRACT

SANTAL MIDY CAPSULES have been prescribed with uniform success for over thirty years. Distilled from carefully selected Mysore Sandal-Wood, the oil is bland and remarkably
FREE FROM THE IRRITANT AND NAUSEATING EFFECTS
which are provoked by many preparations.

There is marked absence of gastric and other disturbances, diarrhœa and skin eruptions. Its mild chemotactic properties permits its administration in relatively large doses without fear of too violent reaction or intolerance.

SANTAL MIDY CAPSULES may be prescribed and relied upon in all stages of Gonorrhœa and in other forms of Urethritis and affections of the Genito-Urinary tract.

The Capsules contain 5 drops, and usually 10 to 12 are given daily in divided doses.

Prepared in the Laboratoire de Pharmacologie Generale, 8, Rue Vivienne, Paris, and sold by most Chemists and Wholesale Druggists throughout the World

U.K. Agents: WILCOX, JOZEAU & Co, 15, Gt. St. Andrew St., W.C.2.

A·K

SANTAL MIDY

This preparation is now obtainable in 5-oz. bottles.

MIST. DAMIANÆ CO. (HEWLETT'S).

MIST. DAMIANÆ CO. (Hewlett's) will be found to possess all the properties of Damiana, viz.:—Its alterative effects on the alimentary canal and tonic action upon the brain and nervous system generally.

In all the various forms of loss of nerve power Mist. Damianæ Co. (Hewlett's) is a powerful remedy, relieving the exhaustion and conferring renewed capacity for mental and physical endurance.

As a nerve tonic and brain stimulant it is unequalled, and its invigorating properties will be found invaluable in many diseases where there is great depression and exhaustion. In paraplegia, hemiplegia, and partial paralysis it is particularly indicated, and may be suitably and satisfactorily employed wherever a powerful nerve stimulant and restorative are required.

Dose: One or Two Drachms in Water.

Packed in 5-oz., 10-oz., 22-oz., 40-oz., and 90-oz. Bottles. Price in England 12/6 per pound.

Introduced and Prepared only by

C. J. HEWLETT & SON, Ltd., 35 to 42, Charlotte St., London, E.C.2.

Infantile Diarrhoea.

A letter recently received.

The Medical Adviser of Messrs. Kaylene Ltd.,
London.

Dear Sir,

The case to which I referred was a child of six months who was brought to me after having treatment elsewhere for diarrhoea and vomiting. The child was practically a skeleton and apparently had been vomiting everything—even medicine—for many days. The mother thought, and her friends thought, the child was dying, and I happened to be the nearest doctor. I gave the child one teaspoonful of plain Kaylene in plain, cold, boiled water, and kept the mother and child in my consulting room to watch effects. If ever a child was drawn from the jaws of death, I think that little sufferer was. The Kaylene was retained; the gasping steadily lessened; the haunting look of that child's eyes became less distressing; in fact, the change for the better was so pronounced that in an hour's time I allowed the mother to take the child home.

Fortunately, I had sufficient Kaylene by me (a sample you kindly sent), and I gave the mother sufficient to give a teaspoonful every hour during the night. The chemists' shops were all shut by this time. I gave full instructions—strict instructions—not to give anything else but Kaylene and plain, cold, boiled water as I had done.

In the morning the mother came to see me and informed me that only twice during the night the child had loose stools but no vomiting, and had slept fairly well. The child had other two loose motions during the day, but *not offensive ones like all the other stools. In the evening the child cried—the first time for two days—and as she* looked, and was, so much better, I gave her some white of egg with plain, cold, boiled water. Still improving, I kept her on this for three days. She was doing well and I then allowed her milk. She made a complete recovery, and there can be no doubt whatever that Kaylene saved the child's life

Yours faithfully,

....., M.B., C.M.

MEDULLA RUBRA

BONE-MARROW IN ANAEMIA FROM HAEMORRHAGE

W. Peterhans (*Deut. med. Woch.*, March 28th, 1930, p. 521) reports the results of his experiments on young dogs in which anaemia had been artificially produced by the removal of about half their blood. In the first series of the animals were fed with rib marrow, others with marrow from the long bones. Control animals received a corresponding amount either of fat or of liver extract. The basal diet in each case contained a small amount of iron (5 mg. per cent.). Only the animals receiving the rib marrow showed a definite increase of weight, and their haemoglobin formation was more rapid than that of the others. In the next series the experiment was repeated, but the iron content of the diet was reduced to 1.4 mg. per cent. The result was similar but more striking, the dogs receiving the rib marrow regaining their haemoglobin far more quickly than the others.

THIS extract from the "Epitome of Literature," published in the "BRITISH MEDICAL JOURNAL," dated May 3rd last, is important as representing, in 1930, a complete justification of the formula upon which

Roboleine

THE FOOD THAT BUILDS THE BODY

has been produced without variation during the past twenty-five years.

The success of ROBOLEINE is thus due to intelligent anticipation and to consistently maintaining the highest possible standard of manufacture.

Medical Practitioners are asked to satisfy themselves of the merits of ROBOLEINE, for which purpose testing samples will be gladly sent upon request.

Dimol

the Safe and Effective Intestinal Disinfectant

Before the discovery of Dimol the use of intestinal disinfectants was discredited owing to the impossibility of administering anything which was non-toxic to the host in the necessary dosage to produce the desired result.

Dimol does not liberate phenol in its passage through the intestinal canal—it is not split up or absorbed, nor does it enter into combination with other drugs. When it comes in contact with the pancreatic fluid it is emulsified and goes forward with the faeces and is voided unchanged.

The dose recommended for Dimol is 2 to 4 pulverettes—say 3. Each pulverette contains 1 gr. Dimol, and Dimol is 35 times more efficient as a bactericide than Phenol; that is to say, in administering 3 Dimol pulverettes the patient is receiving the bactericidal equivalent of 105 grains of Carbolic Acid.

After long and careful investigation at the Royal Naval College, Greenwich, Dimol Pulverettes are now being issued by the Admiralty for use in His Majesty's Ships and Royal Naval Hospitals.

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

"Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidal Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic and Sedative, "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

THE FRENCH NATURAL MINERAL WATER

VICHY-CELESTINS

And the other State Springs of Vichy
(Property of the FRENCH STATE)

FERMENTATIVE DYSPEPSIA

When the secretion is vitiated in quality, and the motricity of the stomach weakens, that organ dilates, and the gastric stagnation allows the micro-organisms of many ferments to develop. Quite a series of acids are then to be met with (butyric, lactic, acetic, etc.), which not only irritate the mucosa, but further, after their passage into the intestine, become absorbed by the lymphatics and swept into the circulation. **Vichy-Celestins**, by its slightly stimulating action, clears out the stomach, and this avoids stagnation and consequent fermentation. As, in addition to doing this, it modifies stomachal metabolism, the secretions return little by little to their normal physiological condition.

CAUTION.—Each bottle from the STATE SPRINGS bears a neck label with the word "VICHY-ETAT" and the name of the SOLE AGENTS:

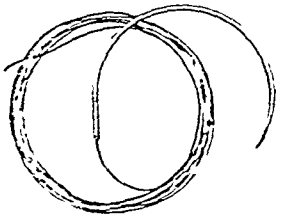
London Hospital Eyeless Needles

WITH L.H. CATGUT



The London Hospital Eyeless Needles have been specially designed to avoid the doubling of the suture necessary in using needles with pierced eyes. They are fitted with tubular ends into which the sutures are firmly fixed, thus enabling the needles to be used with single strands. These needles are finely ground, sharp pointed and packed sterile in tubes for immediate use. Special precautions are taken to avoid any rusting of the needle after it has been packed.

RHEUMATOID ARTHRITIS

UNDER this name, several conditions which are ætiologically distinct are doubtless grouped together, and we are still far from a solution of the cause of the disease.

It is obviously impossible to restore in any marked degree mobility to the joints of the hopelessly crippled, but in the early stages much may be done to retard or stop the progress of the disease.

An eminent surgeon has directed attention to the rôle of chronic intestinal stasis and alimentary toxæmia in the production of the disease, and has emphasised the need for intestinal disinfection.

For this purpose nothing surpasses the use of Kerol Capsules. Kerol is a potent and non-toxic germicide which is unabsorbed from the intestine, so that the whole of its germicidal power is exerted upon the contents of the bowel.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

INTESTINAL SUBINFECTION

SALVITAE is the key whereby the physician may control elimination and alkalinization, thus dealing fundamentally and effectively with Intestinal Subinfection, Toxæmia, Acidosis, Uric-acidæmia, and Constipation.

It is indicated in a large number of disorders characterized by, and more or less dependent upon, faulty metabolism, imperfect elimination, and disturbances of the acid base equilibrium of the body.

The "Allenburys"

"CHARKAOLIN"

GRANULES

"Charkaolin" is a highly efficient agent for the treatment of intestinal infections characterized by abnormal fermentation and the formation of toxins. It combines the absorbent properties of highly activated vegetable charcoal with the well-known toxin-adsorbing qualities of "Osmo" Kaolin.

It is in the form of fine, clean granules which disintegrate rapidly in water and diffuse their ingredients evenly throughout the liquid. "Charkaolin" is tasteless, forms a fine suspension in water and is, therefore, quite easy to take.

In bottles at 2/6 each.

TABLETS

The "Allenburys" "Charkaolin" Tablets provide a convenient alternative method of administering "Charkaolin." Particularly suitable when travelling. Tasteless and disintegrate readily

In bottles:
40 tablets - 1/6
80 tablets - 2/6

MAP ILLUSTRATING THE ARABIAN EMPIRE AT ITS GREATEST EXTENT.—When Mahomet arose and achieved the unification of the whole of the Peninsula, Arabia became the centre of an irresistible power, which, spreading rapidly east and west, overthrew the existing social framework—Byzantine and Persian—and imposed its own religion, organisation and way of life. The great outward expansion was achieved after Mahomet's death—between A.D. 635 and 641, when Syria, Iraq, Egypt and Persia were embodied in the new empire. The Arabs pushed westward in North Africa and established themselves in Morocco during the eighth century. The greatest of their conquests—that of Spain—was made in the short space of two years, A.D. 711-712.

THE TECHNIQUE OF RADIUM THERAPY TO-DAY.*

BY

DUNCAN C. L. FITZWILLIAMS, C.M.G., M.D., CH.M., F.R.C.S.,

SURGEON AND LECTURER IN CLINICAL SURGERY, ST. MARY'S HOSPITAL.

RADIUM therapy has been dealt with largely by the lay press, which has done much good in educating people in the subject, but, as is so often the case, a false impression has been given by the application of the journalistic touch to a most important subject. Two erroneous views are, I think, widely held by the laity in consequence: one is that radium will cure all cases of carcinoma, and the other is that for want of radium many unfortunate people are dying daily throughout the country.

The use of radium has now reached a position where we know that in the treatment of carcinoma it is on a par with the knife, and in certain cases surpasses the use of that instrument; but even the knife has never been able to deal with all cases of carcinoma. In the second place, *there is at the moment more radium in this country* than there are people trained and capable of using it. On the Continent radium has been studied for many years, while in this country scientific methods have been comparatively lately introduced.

Radium gives off three forms of rays: alpha rays, which are of no importance; beta rays, which are disadvantageous for medicinal purposes, and must be screened off by platinum, lead, or other impermeable metals, since they destroy normal as well as abnormal tissues; gamma rays, which produce therapeutic effects, but must be as pure as possible. *The gamma rays act more powerfully on immature* tissues than on fully developed and highly differentiated ones. Cancer cells, being immature and hardly differentiated—in many cases consisting of masses of almost wholely undifferentiated cells in stroma—are very much more sensitive than the normal tissues. They can therefore be killed without permanent injury being inflicted upon the normal tissues. We also know that cells in the course of rapid division, such as cancer cells, are more sensitive than cells which divide and multiply at longer intervals.

METHODS OF APPLYING RADIUM.

General radium therapy is the introduction into the system of radio-active substances which will circulate throughout the body and act upon the primary growth, the glands, and the metastases. It is the ideal method, but unfortunately at present it is beyond our powers, since the introduction of such substances would injure vital organs and the individual would be killed before the carcinoma could be destroyed. The future may reveal to us a means of treating carcinoma by this method, and the introduction of a vaccine, a serum, or a metal such as lead, or selenium may open up to us a way of approaching our ideal. Meanwhile we are limited to the introduction of radium foci locally. Radium acts in accordance with Newton's law—that is, its action is the inverse of the square of the distance from the substance on which it operates; these foci must therefore be brought into close contact with the carcinoma, and in order to do this it is convenient to have many foci so that the dose may be evenly distributed over a large area.

Radium must not be confounded with its emanation—radon—which is collected in capillary glass tubes and which acts like radium, though only for a very limited time. In twenty-four hours it loses 18 per cent. of its power; in three days 50 per cent.; in eight days 80 per cent.; while in fourteen days only 8 per cent. remains. This limits its use to centres where a radon plant is available, otherwise exact dosage is difficult or impossible to calculate, since it is not always known when it was prepared and how much has been dissipated.

Seeds are tiny glass tubes filled with radon, which may be enclosed in a platinum sheath to shield the tissues; they are about 6 mm. long and less than 1.5 mm. thick. Various instruments have been invented for their introduction. They are inserted into the tissues and left there, the radon dissipating in the usual time; if they contain radium they must be attached to a silk thread and recovered.

Needles contain radium in metal capillary tubes called "cells," which are enclosed in platinum tubes, sharpened at one end and with an eyelet at the other. They are of different lengths, and contain one, two, or more cells, each containing 0.5 to 1 mg. of radium. Needles range in length from 20 mm. to 60 or 80 mm., and differ in strength according to the number of cells they contain. The needle is threaded with a flexible substance or thin wire, and is then thrust into the tissues; after a certain time it is recovered by traction on the thread. The thickness of the wall of platinum in each needle varies from a minimum of 0.5 to 0.8 *mm., or even 1 mm. for* longer needles.

Tubes are composed of platinum, and contain larger quantities of radium ranging from 5 to 100 mm. or more. As a rule they are of no great length, 20 to 40 mm., while their walls may be 2 mm. in thickness. As a rule they are placed in special containers of silver, which fit the situation in which it is desired to place them —the uterus, rectum, or oesophagus.

Bombs are thick leaden cavities, sometimes six inches in thickness, in which large quantities of radium (perhaps 4 grams), suitably screened, are placed; a window can be opened, and the rays allowed to act upon the area required for a very short time. They have been tried in Brussels and Paris, and now there is one at the West*minster Hospital. Though they have been in use for some* years abroad it is significant, I think, that, so far, no results have been published.

The dose of radium should be distributed as equally as possible over the malignant cells so as to destroy them, while avoiding injury to the surrounding tissues. This is not always easy to effect. In a large tumour the cells in the centre cannot escape, and can probably do nothing *but degenerate; they are therefore not to be feared, for* the actively growing and infiltrating cells at the margin are the agents by which spread and metastases are brought about.

In a flat ulcer needles can be introduced into the tissues underneath, and can be placed parallel; but in deeply *situated growths infiltrating the tissues, such as the tongue,* the needles have to be arranged parallel with the sides, so that they gradually converge from the surface.

1. *The Internal Method of Application, or Intra-cavitation.*—This is the introduction of radium into a natural cavity such as the vagina, uterus, rectum, mouth, or oesophagus. The radium is kept in place a certain time to allow it to take effect, and special apparatus may be required; for instance, a dental plate may have to be used to keep the radium in contact with a growth of the palate. Considerable experience is needed to gauge the dose required.

Internal radium therapy is limited in action by many factors, such as the depth from the surface in the oesophagus and rectum, by the thinness of the walls in the oesophagus, or the narrowness of the tube in the urethra. For instance, in the urethra or oesophagus it is almost impossible to destroy a growth on one side and not injure the wall of the canal on the other; this has been a frequent cause of death in cases of disease of the oesophagus.

Perhaps the best results have been obtained in cases of carcinoma of the cervix. The uterus is an organ possessing great radio-resistance, and will stand ten times the dose that the skin will tolerate, so that there is a large margin to work on. The figures of Paris, Stockholm, and Brussels do not differ materially, so I will take those of Paris.

The cases are divided into three classes: degree 1, operable cases in which the carcinoma is apparently early and local; degree 2, borderline cases where the disease is in a more advanced state on the cervix, and the glands

[3634]

*A British Medical Association Lecture (abridged) delivered before the South Wales and Monmouthshire Branch of the British Medical Association on May 31st.

are possibly affected; degrees 3 and 4, inoperable cases, where the disease is still more advanced, and the adnexa of the uterus are infiltrated. In degree 4 other metastases are present, and the case is hopeless.

In the Paris report there were 61 available cases; the number freed from symptoms was 37, or 60 per cent. of clinical provisional cures. The percentage of five-year cures increased from 20 in 1919 to 81 in 1923. In degree 2 there were 176 available cases, of which 66 were freed from symptoms, or 37 per cent. of clinical provisional cures. The percentage of five-year cures increased from 33 in 1919 to 43 in 1923. In degrees 3 and 4 there were 373 available cases; 81 were freed from symptoms, or 28 per cent. of clinical provisional cures. The percentage of five-year cures increased from 3 in 1919 to 31 in 1923.

These figures are as good as those of the best surgical clinics, and have improved remarkably during the last few years. They probably will improve still more, but all cases will not be cured. There is a great difference in the percentage of cures among those seen and diagnosed and treated early and those seen at a later date. Although squamous-celled carcinoma of the cervix gives such good results, adenocarcinoma of the body of the uterus is highly resistant and gives very bad results; indeed, its treatment by radium has practically been abandoned.

2. *Interstitial Method.*—This consists in the introduction of needles into the tissues. In order that the dose may be evenly distributed a large number of foci or needles are required. Interstitial radium therapy is applied to a host of tumours throughout the body—to either carcinoma or sarcoma of the tongue, the breast, the prostate, or to superficial ulcers and metastases. Carcinoma of the skin gives perhaps the best results; about 90 per cent. can be cured either by this method alone or in some combination.

The tongue yields very striking results, and again I will cite the Paris figures. Of 344 available cases complete cure ensued in 82 (23 per cent.); cure of the tongue, with death from glandular involvement, in 69 (20 per cent.); and failure in 193 (56 per cent.). This far surpasses any results produced by surgery so far.

Interstitial radium therapy has been developed by what is termed "radium surgery" or "surgery of access"; in this the tumour is exposed so as to allow the needles to be inserted. This is best exemplified in carcinoma of the rectum where a modified Kraske operation is performed; the bowel containing the growth is exposed, the needles are inserted so as to form a barrage round the tumour, and the wound is temporarily closed. At the end of a week the wound is reopened, the needles are removed, and the wound is then permanently closed. Very accurate dosage is needed to destroy the tumour, and the method so far is inferior to the knife. Investigation is rapidly travelling along these lines; carcinomas of the larynx and of the prostate are being treated thus, the first with unexpectedly good results.

3. *Surface Irradiation.*—If radium is applied close to the skin an erythema dose is delivered over a very small area, and a burn is rapidly produced. Columbia paste or wax, consisting of 100 grams each of beeswax and paraffin, with 200 grams of fine sawdust, is used, either 1.5 or 2 cm. in thickness. This allows the rays to spread out sufficiently so that an erythema dose will take some time, and the radium can act longer on the subjacent tumour. The wax is warmed in hot water of about 117° F. until it is as soft as a piece of cloth; it is then moulded to the part, a cold cloth being applied to harden it, and the hardening completed by plunging the mould into cold water. The needles are warmed and applied to the outer side; they will stick to the mould or can be fastened to it by plaster, and are covered with a thin layer of lead to protect other parts of the body. The mould is kept in place for fourteen to twenty-one days, until an erythema dose has been administered. Large areas can be irradiated in this manner with very excellent results, especially in superficial metastases.

4. *Distance Radiation.*—This consists of a similar apparatus to the last, but large doses are placed upon blocks of wood at a distance from the skin. It is becoming less and less used. Bombs are a development of this method.

DOSAGE.

The dose of radium given is usually stated in milligram hours; the number of milligrams applied is multiplied by the number of hours of exposure given. Thus 1,000 mg. of radium applied for one hour will equal 1,000 mg. hours, but the same dose can be given by 1 mg. of radium applied for 1,000 hours, or 500 mg. for two hours, or 100 mg. for ten hours, but the clinical results will not be the same.

In early days large doses were given for short periods, but the work of Professor Regaud of Paris showed that large doses with short exposures did not sterilize rabbits, while smaller doses for longer periods did so. This is probably connected with the division of cells, for more mitoses will take place over a long period than over a short one. On the other hand, we know that exposure to radium stops mitosis at once, so there must be some other factor not yet understood. This has revolutionized our dosage, and we are using smaller doses over longer periods. Such a method of dosage is only rough-and-ready, for while needles inserted into the tissues give off energy all round to the tissues, when radium is applied to the skin, the skin will receive less than half the energy given off. In Brussels an attempt is being made to measure accurately the dose received by the tissues, and it seems probable that our methods of dosage will be altered very considerably in the near future.

All degrees of burn can be produced by radium. The first degree is called the erythema dose, and it is tried to bring about a severe first degree of burn where the skin peels afterwards. More than this destroys the tissues, and such burns take long to heal and are painful; they should therefore be avoided. Radium is believed to act best in a virgin soil, and a second dose some months later does not seem to produce as good results as the preceding one. If a second dose follows after only a short interval the same good results are seen. Gynaecologists have developed this idea; they give three doses at intervals of a few days, with excellent results, in carcinoma of the breast.

RESULTS OF RADIUM THERAPY.

The results of radium are well seen on superficial growths on the skin and mucous membranes; the surface cleans up, and becomes smooth and healthy-looking; the rolled-over edges of an ulcer disappear, the mucous membrane becomes white like leukoplakia, and within a week a marked improvement is seen. These changes remain for a period of five to eight weeks, during which time healing advances, and in about two to three months a carcinoma of the tongue may quite disappear. A superficial rodent ulcer will heal in the same time; if, however, it is of long standing and the bone is affected it may take longer to clear up completely. Tumours of the breast will disappear if not too large, and superficial recurrences will certainly clear up, while carcinomatous ulcers can be made to heal, but others may form, or the patient may succumb to internal metastases which have previously started to grow.

One remote result must be remembered. After exposure to radium the tissues are altered, and some quite slight injury may cause their death and necrosis. What this change is we do not know, but we see necrosis of the jaw develop from wearing false teeth, death of areas of skin appear after too hot a bath, and other results ensuing months after the treatment. Healing is very slow, and subsequent operations have to be very carefully considered. This change is not seen earlier than two months, and sometimes more.

THE LIMITS OF RADIUM TREATMENT.

Many of the present limits of radium treatment will probably be overcome in the future; accessibility of the growth is a fundamental necessity. For this reason carcinoma of the oesophagus defies us, though surgery of access enables us to expose the rectum. This may soon render it possible to deal with intestinal carcinoma, but at the moment we can do little. Gastric cancers have been brought to the surface, stitched under the skin, and then treated, but prolonged relief can scarcely be looked for in internal carcinomata which are only suspected from symptoms and which are therefore diagnosed late. Cancer

of the prostate is in the same unenviable position, being diagnosed late and being inaccessible.

Sometimes a carcinoma in its primary form readily reacts to radium, but the glands when infected may not react at all, block dissection of the glands still seems the best treatment in carcinoma of the tongue. Some carcinomata, such as that of the body of the uterus, are resistant and not apparently affected by radium. *Accuracy of dose* in all cases is essential, and that is the great difficulty at the present moment.

Cure is a term we hardly like to use in connexion with carcinoma, for though a round-celled sarcoma may disappear in a few weeks, the patient will probably die from secondary infection in the lungs, just as after an amputation. Delay, however, is less likely with radium, for there should be less shrinking from radium treatment than from amputation. If it can be impressed upon the public that early diagnosis will remove the disease without a mutilating operation a bigger step forward will result than has ever been made in the history of this disease.

THE FUTURE OF RADIUM TREATMENT.

It must be clearly understood that the treatment of carcinoma by radium requires the knowledge and the experience of a specialist. Haphazard administration must involve disappointment and bring the method into contempt. It is a regrettable thing to have to say that radium treatment in this country has survived in spite of, rather than because of, institutions which have loaned radium to people totally ignorant of the subject; the indiscriminate distribution of radon about the country must cease, and radium centres are now being established to supply the needs of different areas. France has already formed a large number of such areas; an expert visits the centres and even subcentres at regular intervals.

Post-graduate teaching is now available at the Mount Vernon Hospital, which, it is hoped, will become the cancer centre of the Empire, and attract research students to it from all parts. This institution has linked itself with the Radium Institute, and a school will be opened in the autumn for the instruction of post-graduates in radium treatment. Very close co-operation is needed between the different branches of the profession, including surgeons, laboratory workers, biologists, and physicists, this has been brought to a high state of efficiency in Paris, Brussels, and Stockholm, and the results there are correspondingly good.

No carcinoma investigation is worth anything unless a really good follow-up department is in use. A patient may be relieved for a time, and a secondary mass appear, which can be dealt with efficiently if seen and recognized at once; patients must therefore be examined at all centres periodically. It is hoped that special travelling facilities by rail may be arranged so that they can come for examination at the London centre of the hospital at a reduced fee. In Sweden all carcinoma patients can travel to the centres free of charge. Results cannot be expected until five years have elapsed, so patience is needed, but it is hoped that organization will soon place London in the forefront of the battle against malignant disease.

THE TREATMENT OF PRURITUS ANI AND ANAL FISSURE.

BY

W. B. GABRIEL, M.S.,

SENIOR ASSISTANT SURGEON, ST. MARK'S HOSPITAL

RECENT communications to the *British Medical Journal* by J. P. Scatchard (June 28th, p. 1203) and by A. S. Morley (July 12th, p. 79) indicate that the treatment of anal pruritus and fissure by the method which I described a year ago[1] is proving successful. The method recommended was the subcutaneous injection of a solution composed of anaesthesin 3 *per cent.*, benzyl alcohol 5 per cent., and ether 10 per cent., in sterilized oil, and termed "A.B.A." Since the publication of that paper I have had a large experience of this method, and the present time seems favourable for the elaboration of certain points in the indications and technique which I have found of value.

Pruritus Ani

In pruritus ani it is only the intractible cases which need treatment by injection of A.B.A., the majority of cases will clear up by simple attention to cleanliness, by the use of lotions and powders rather than ointments, and by careful search for and treatment of any local cause of the pruritus. The attention which has recently been drawn by Colonel W. P. MacArthur (*Journal* June 28th, p. 1195) to the importance of threadworms in this connexion is very opportune. In cases of pruritus ani of long standing in which no local cause can be found, I believe the injection of A.B.A. to be the method of choice, and superior in every way to under-cutting operations. With increasing confidence in the use of this solution, I have found that 10 c.cm. may safely be employed at the first treatment. This amount is injected in relation to the posterior half of the perianal region through four punctures, 2½ c.cm. being injected at each point indicated in the accompanying diagram (Fig. 1). The reason for selecting this part for the first injection is an anatomical one. The sensory nerve supply to the anus and anal canal is supplied by the inferior haemorrhoidal nerve, and by the perineal branch of the fourth sacral nerve; these nerves approach from the posterior and postero-lateral aspects of the anus. An injection of 10 c.cm. of A.B.A. as described above gives the pruritus, so to speak, an immediate knock-out blow, and very little more has to be done. A week later 5 c.cm. of A.B.A. are injected by two punctures into the right anterior anal quadrant (Fig. 2), and the left anterior anal quadrant is dealt with similarly during the following week. Perianal dermatitis is treated on the accepted lines, cracks and fissures are swabbed with silver nitrate solution, iodine, or friar's balsam, and the patient applies a simple lead or magnesia lotion. Relief of irritation is experienced within a few hours after the first injection. A feeling of numbness develops and lasts for many weeks, so that ample time is afforded for treatment of the dermatitis, and for the patient to forget his anal troubles.

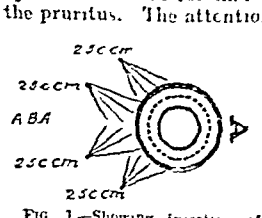

FIG. 1.—Showing injection of 10 c.cm. of A.B.A. into the two posterior quadrants at the first treatment.

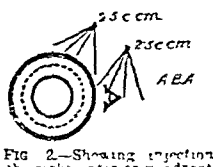

FIG. 2.—Showing injection of the right anterior quadrant at the second treatment. At the third session the left anterior quadrant is injected in a similar way.

In the average case, therefore, I find that the injection of three doses—10, 5, and 5 c.cm.—of A.B.A. is sufficient for cure. I have given this large dose many times and have had no complications. The solution must be injected deeply in a fan-like manner as described in my original paper, with strict attention to asepsis, and the injection should be made so deeply that no superficial swelling is noticeable afterwards. I might add that A.B.A. is now dispensed by Messrs. Allen and Hanburys in 5 c.cm. ampoules, which is a more effective amount for use than the original 2 c.cm. ampoules.

As an alternative to A.B.A., I have for some months been trying a solution of percaine in oil, the remarkable anaesthetic properties of this substance in regard to duration of anaesthesia are well known. The new solution has been prepared for me by Allen and Hanburys, and is composed as follows: percaine 0.5 per cent., benzyl alcohol 10 per cent., phenol 1 per cent., in 5 c.cm. of sterilized oil. The phenol was added in order to assist the solution of percaine, alkalis having to be avoided, and also on account of its antiseptic effect. Goldbacher[2] has shown that 5 per cent. phenol in oil can safely be injected subcutaneously in pruritus cases. This new solution produces a more rapid effect than A.B.A., and the duration of the

hypo-aesthesia in cases of pruritus is very satisfactory. The percaine content in 10 c.cm. of this solution (0.05 gram) is well within the limits of safety for adults, and I have only once had any general reaction: this was in the case of a man with pruritus, who, on a hot summer's day recently, became slightly pale and faint after the injection, but quickly recovered.

Anal Fissures.

In the case of anal fissures, A.B.A., or the percaine in oil solution, can be trusted to produce sphincteric relaxation, 5 c.cm. being the usual amount which I now inject into the sphincter. A superficial fissure will heal readily: a fissure with a sentinel tag will heal when the tag has been snipped off, but it is not possible to secure healing of a deeply undermined fissure without a drainage operation. A fissure of this last type is really a submucous pocket or a blind internal fistula, and must be drained back by a surgical operation. Injection of A.B.A. in such a case may relieve the symptoms, and will permit a thorough examination to be made, but it will not cure the condition.

The operation for drainage of a deep undermined fissure is best performed under a low spinal anaesthesia by the technique described by my colleague at St. Mark's Hospital, Mr. J. K. Hasler.[3] With the patient in a sitting position 0.4 or 0.5 c.cm. of stovaine billon in saline solution is injected intradurally through any convenient lumbar interspace. The patient remains sitting for a few minutes before being placed in the lithotomy position; he is then found to have a saddle-shaped area of anaesthesia in the perineum corresponding to the distribution to the skin of the fifth, fourth, third, and sometimes the second sacral nerves. The operation is performed as follows. The sphincter is gradually stretched until five or six fingers can be admitted readily. The undermined pocket is then drained posteriorly, and the sentinel tag is excised. Instead of the usual "lozenge" or diamond-shaped incision which has hitherto been recommended, I now make an incision with square ends, which has great advantages; it gives better drainage, and renders healing of the wound in the anal canal quite inevitable (Fig. 3).

Fig. 3.—Indicating incision with square ends, recommended by the author for drainage of a deeply undermined fissure.

ANAESTHETIC EXPLOSIONS.

BY

K. B. PINSON, M.B., Ch.B., M.R.C.S., L.R.C.P., A.I.Mech.E.,

ANAESTHETIST, MANCHESTER ROYAL INFIRMARY.

Two cases of alleged explosion of chloroform vapour have recently come to my notice. Chloroform is not inflammable; in fact, it cannot be made to burn by itself. A mixture of 2 parts of chloroform with 1 part of ether, or a mixture of chloroform, alcohol, and ether will, however, burn, giving off strong acrid fumes containing chlorine.

I have tried to discover whether in favourable circumstances the vapour of chloroform can be caused to ignite, for in one case there was an explosion when an electric cautery (Cameron's "cauterodyne") was being used in the mouth. I first passed a stream of oxygen through chloroform in a Junker's bottle, and failed to ignite the vapour issuing from it. I thought that the extremely high temperature of the electric spark might in some way render the oxygenated vapour combustible, so I prepared an experiment in which chloroform was boiled in a tin canister with a stream of oxygen bubbling through. The flame of an oxy-acetylene blowpipe was applied to the vapour, and, subsequently, a fragment of steel was kindled in the vapour with the aid of a jet of oxygen. This procedure resulted in such brilliant scintillations being given off that the heat must have been well over 4,000° C.—the temperature of the flame—and at least as high as the sparks from the electric cautery.

In both cases the chloroform vapour decomposed at once into billows of pungent and acrid black fumes; these did not catch fire, and the decomposition did not continue when the flame was removed, indicating that it was not the chloroform vapour that became ignited in the two cases. Since there is no doubt at all about the facts in the two cases of explosions at operations, I can only say that the occurrences must have been caused either by the inadvertent addition of ether, or by the burning of combustible gases arising from hot and charred tissues in such a confined space as the mouth. This is a probable explanation in the second case, and accounts, of course, for the flickering always seen when using such cauteries.

At least a hundred explosions probably occur every year with ether in this country, causing trifling or severe burns of the eyebrows, lips, and pharynx, but not extending into the lungs, because the mixture is too weak to burn there. The explosions are caused by the ignition of the richer mixture introduced into the mouth by a tube or occurring in the immediate proximity of the soaked coverings of the mask. I feel sure that two or three minutes after stopping the administration of ether the expired air contains too little of the gas to ignite.

For several years I have continually used the ether bomb apparatus, often within two or six feet of an open fire, and frequently much nearer a cautery, without any ignition taking place. The quantity of ether is too small, or too quickly diluted, although, where there is an electric radiator in the room, the pungent fumes of slow combustion can always be smelt above it within a few minutes of the vaporization of even a small quantity. An explosion was reported to have occurred from the introduction of the apparently sound lamp of an oesophagoscope into the pharynx; it must be concluded that the connexion in the lamp socket was sufficiently imperfect to cause minute sparkings, because I have found that a needle introduced into an air-ether mixture has to be at least red-hot to ignite it.

The ordinary optimum mixture of petrol vapour and air in a motor car engine is 1 in 13; in the case of alcohol it is, I believe, 1 in 14, and in that of ether the proportion is probably the same. A weaker mixture would, however, ignite, and so would a stronger, but the limits (without compression) are not wide and the ignition point is considerably raised. When a combustible gaseous mixture is raised to a certain temperature it "fires"; this is its "ignition point." The term "flash point" refers to a liquid, being that temperature at which it gives off inflammable vapour. The temperature at which a hot body introduced into an inflammable mixture will cause ignition depends partly upon the nature of the body.

In this connexion a case was recorded in the *British Medical Journal* of October 17th, 1925, where a dental warm air syringe set fire to ether vapour in the mouth of a patient and resulted in fatal haemorrhage. The nearest flame was said to have been six feet away, and the nozzle of the syringe was certainly not red-hot. In the correspondence which followed this report the possibility of catalytic action, similar to that induced by spongy platinum, was mooted, and also the chance of burning spirit being carried on to the nozzle from the lamp employed to heat it. I can find very few references to explosions.

By far the most serious fires with ether have been caused by bottles being dropped in rooms with open fires or electric radiators. Ethyl chloride will not ignite in air, but it burns with an apple-green flame on the addition of a little extra heat, and more freely with oxygen; curiously enough, however, the condensed substance burns freely with a luminous and smoky flame, which is coloured green near the liquid surface. The explanation of this may be that the jet of gas becomes too rapidly diluted with air, partly owing to the velocity at which it passes out of the nozzle.

In the case of ethylene and acetylene the matter is more serious. I have never used the latter as an anæsthetic, but I give an oxygen-ethylene mixture for dental surgery as a routine, because I find it better than nitrous oxide. I have been told that bad explosions have occurred with both these gases, and that fatal consequences have ensued. In these cases, however, an explosive mixture exists not only in the patient's lungs, but in the bag used, and there is a grave risk of an explosive mixture accumulating in a room since so much larger quantities are used. With even saturation in a small room of 1,000 cubic feet a cylinder of 500 gallons would have to be emptied to provide with air a mixture of 1 in 12. This is a considerable volume of ethylene, but saturation will not ordinarily be even; an accumulation of sufficient concentration is always present near the facepiece, so that a lighted cigarette (or, it is conjectured, a spark from a static charge gained by the gas in issuing from the cylinder union) could cause a violent and tragic explosion.

Dr. F. W. Higgins, working at Manchester University in connexion with mining gases, found that the ignition point of an oxygen-ethylene mixture was unusually low, and that the ignition point of a nitrous oxide ethylene mixture was still lower. In dental practice I use quantities of 10 to 50 gallons frequently, with nitrous oxide and oxygen added, *often in a room containing an open fire.* I am careful about lights (dentists often have a small Bunsen burner alight) near the patient. A short time ago I kept a man under with an oxygen-ethylene anæsthetic mixture in a dental chair for over an hour and a quarter with nothing but a nose-cap; his condition afterwards was not abnormal.

In view of the likelihood of minute sparking in lamp holders, whether of the ordinary design (bayonet) or any other, I dislike electric lights too near. Where they have to be used it is advisable to make sure that the electrical connexion between the lamp and the socket is sound

CEREBRAL HAEMORRHAGE IN A YOUNG WOMAN.

BY

S. CHARLES LEWSEN, M.R.C.P.LOND.,

MEDICAL OFFICER TO OUT-PATIENTS, ROYAL CHEST HOSPITAL, CITY ROAD

THE following case presents several features of interest, being the account of an apoplectic fit actually observed during a medical examination, so that an opportunity for first-hand information of its onset and progress was presented. It may be recalled that in *The Story of a Surgeon* Sir John Bland-Sutton mentions a case that he personally observed. The type of hyperpiesia in the present case is also discussed, and the occurrence of an unusual example of automatic speech is described.

A school teacher, aged 30, consulted her doctor because of painless haematuria, and was found to have a systolic blood pressure of about 300 mm. Hg. In consequence she was admitted to the Prince of Wales's Hospital under Dr. Browning Alexander to be investigated. The patient had had measles and chicken-pox as a child, but no scarlet, rheumatic, or other severe fever. Her appendix had been removed five years previously, and she had diphtheria severely a year later, being confined to bed for two months. Subject to headaches for many years, she had suffered more acutely for the last three months. Occasionally there was an aura of black spots, and she had often felt sick during the attacks, though vomiting was rare. Two months before admission she had an attack of severe backache, which persisted for five weeks. For two weeks there had been a blurring of vision in the right eye, and she remembered a similar blurring in the left eye some time back; latterly her nose had bled on two occasions. There had been no frequency of micturition, and the menses were always regular; latterly she had felt breathless at times, and had had palpitations. None of the symptoms troubled her sufficiently to seek medical advice until the appearance of blood in the urine a few weeks before admission. There was nothing of importance in the family history.

Condition on Admission

The patient was thin; the skin was rather dark and the eyes were perceptibly prominent. The thyroid was not enlarged, but the tonsils were definitely infected.

The pulse was regular, forceful, and rapid (110 to 120 per minute). The radial artery was tough and tortuous, and the blood pressure was 280/210. The apex beat was just out of the nipple line; the sounds were forceful, but no bruits were heard.

The basal metabolism inferred by Read's formula was +8. No abnormalities were found in either the lungs or abdomen. The pupils were equal and the reactions normal. The biceps, triceps, supinator, knee- and ankle-jerks were present and equal, the abdominal reflexes were not obtained, and the plantar reflexes were both flexor. The muscles were small, but their power was good.

The Stroke

At 6.45 p.m., directly after the blood pressure had been taken and the preceding observations had been made, something amiss was suspected. Whereas a few minutes before the patient had responded to the examination a little nervously perhaps, but otherwise in a perfectly normal manner, an interrogation was now received with eyes open and consciousness apparently undisturbed, but with an abortive effort to speak that resembled the functional aphasia of a nervous person in a witness-box. The words would not form, and the patient smiled her helplessness away. There was confusion, but no anxiety on her face, and believing that she was indeed temporarily unnerved, she was reassured, and the examination was suspended for a few minutes.

Returning after five minutes, the motor aphasia was found to be more definite, and for the first time a facial asymmetry was noticed. The nervous system was then re-examined, and the following facts were observed: a complete right facial palsy; a *flaccid paralysis of the right arm and weakness of the right leg;* a right-sided blunting of sensations of touch and pain; and an extensor right plantar reflex. The patient was quite conscious, and understood all that was said to her. She was restless, anxious, and sweating.

At 7 p.m. amyl nitrite was inhaled, and she vomited a little. The systolic blood pressure was now 160 mm. Hg. She was drowsy, and later she went to sleep. At 11 p.m. she was still asleep, and the hemiplegia was quite complete. The systolic blood pressure was 240 m.m. Hg.

Subsequent Progress

The following morning the patient was conscious but drowsy, when spoken to she smiled, and said repeatedly, "I see." She was incontinent of urine and faeces. The urine contained a trace of albumin, but no blood was detected by chemical tests. The blood urea was 51 mg. per cent. Both fundi showed many old haemorrhages, with one fresh one on the margin of the right disc, otherwise the discs were normal.

On the fifth day following the stroke the sphincter control returned. The patient understood all that was said to her, and read the daily papers with interest, but she was still only able to reiterate "I see." The right-sided paralysis was still present but the jerks were not exaggerated, and the paralysis was still flaccid. No clonus was obtained. The right plantar reflex was doubtfully extensor, the left one flexor. Mr. Flemming reported on the eyes as follows: "Eye movements jerky, but no true nystagmus. No evident paralysis or strabismus. The fundi show a slight neuritis, with much haemorrhagic exudation round the discs. Some radiating lines of exudation from the maculae, as in albuminuric retinitis. Arteries thick, and veins dilated and tortuous."

Towards the end of the second week the speech began to improve. She was able to answer questions, concentrating persistently, but at times the word would not come. Both plantar reflexes were definitely flexor.

One month after the stroke the improvement was more marked, the facial palsy, as well as speech and muscle movement, being much improved. The musculature was very flabby, and there was wasting of the right arm and leg, where the jerks were difficult to elicit. The right plantar reflex was doubtfully flexor. Sensation remained diminished. The sight was deteriorating, and there was marked swelling of both optic discs.

On the thirty-sixth day she had severe headache, and vomited twice. Following this the power of speech, except for the same phrase of "I see," was lost, but an hour later it had returned to its former level. Four days later the tonsils were enucleated under a general anæsthetic by Mr. Ibbotson, since it was considered they were a definite toxic factor. Bleeding was minimal, and the patient stood the operation very well.

On the forty-seventh day the patient felt faint quite suddenly, consciousness, however, being undisturbed. The pulse rate fell from its usual figure of 100–120 to 70 per minute, and the heart sounds were faint. The pupils were small, and reacted to light sluggishly, but no further changes were noted in the central nervous system. The patient lay quietly, with her eyes closed, but speech was undisturbed. The systolic blood pressure had dropped from its usual height to 165 mm. Hg. One hour later it was 170, three hours later 210; five hours later 220, and eight hours after the onset it was 230 systolic. A similar attack had been noticed by the nurses two days previously.

For nearly two more months the patient continued to progress slowly. The pulse rate seldom varied further than the range of

110–120, the systolic blood pressure kept around 220 mm. Hg, and the temperature remained between 98° and 99° F. Repeated examinations of the urine showed little or no albumin; the daily output averaged about 60 ounces during the first three weeks of her stay, and then gradually dropped to about 30 ounces. The blood urea test was repeated several times, but always gave a figure well within the normal. The Wassermann reaction was negative in the blood and in the cerebro-spinal fluid, a lumbar puncture having been performed ten days after the stroke. The fluid was not under pressure, and no blood pigment was found. The sugar estimation was 0.087 per cent., and the chlorides 0.74 per cent. The right-sided paralysis improved steadily, and towards the end of the period a fair amount of power had returned. The arm recovered sufficiently to enable her to feed herself. Passive and active movements were given daily.

Three months after the stroke the general condition began to deteriorate, and evidence of a failing heart appeared. A low-grade pneumonia set in, the patient became delirious, and the blood pressure gradually fell, so that within a week it had dropped to 140. The urine flow diminished, albumin was found in appreciable amounts, and the blood urea increased to 190 mg. per cent. There was a polymorphonuclear leucocytosis, but the temperature remained subnormal. Death ensued nineteen weeks after the initial stroke.

Post-mortem Report.

The body was thin, and there was wasting of the musculature, especially of the right upper and lower limbs. The lungs showed a terminal congestion, and there were some pneumonic patches at the right base. The heart was small and atrophied; aortic arterio-sclerosis was not marked. The liver showed nutmeg change, and the spleen was small and fibrotic. The kidneys were also small and fibrotic, and there was terminal congestion; the cortex was fairly well preserved.

A large old haemorrhage occupied practically the whole of the basal ganglia of the left lobe of the cerebrum, with the original site in the anterior part, about the level of the genu of the internal capsule. The arteries were not unduly changed, and thickening was not a feature.

Hypertension to the extent exhibited by the patient is of rare occurrence at that age, the more so when it does not fall into one of the three common groups of cardiac, renal, or arterial disease. The kidneys were damaged, it is true, but the changes were consistent with what would be considered a normal response to the high blood pressure; the arteries were surprisingly healthy, and their changes cannot be accepted as primary in origin. Moreover, the two attacks during which the blood pressure fell to normal limits strengthen the opinion that the arterio-sclerosis was slight, and that the contractions and relaxations in these vessels were active movements bespeaking an intact musculature. Most diseases of doubtful origin have been ascribed at various times to infections, both focal and acute; this patient had infected tonsils, and she had had diphtheria four years previously. However, Walker and Hare consider that there is no evidence of pressors in infections, and their figures show that a history of diphtheria is more common in normal people than in hypertonics.

There remains, consequently, the consideration whether the case is to be regarded as one of "essential hypertension," due, as some observers believe, to a constitutional state, inherited as a dominant Mendelian characteristic, and rendered active in response to varied stimuli. Having regard to this possibility, permission was given lately to determine the blood pressures of other members of the family, though further examinations were not permissible. The following were the readings obtained: father, aged 59, 155/90; mother, aged 60, 215/140; sister, aged 29, 130/90; sister, aged 21, 155/90. The mother has had rheumatic fever on two occasions, but is in perfect health, and is not supposed to have any heart involvement. The younger sister was quite well until two years ago, when she was in a mental home for a few months, suffering from depression and delusions of unworthiness which had followed an unfortunate love affair. Her recovery has been complete. There is a brother who was not available for examination. Whereas such a casual examination does not permit of a definite conclusion being stated, there seems to be fair evidence in favour of the view that the patient came from a hypertonic stock, and that her case can be placed in the class of "essential hypertonics" mentioned above.

Sir Thomas Horder, in a recent discussion on high blood pressure at the Harveian Society, spoke of "essential hyperpiesia" as being possibly the expressio flame of endocrine disturbance, adrenal, pituitary, patient certainly exhibited symptoms attributable to a thyro-adrenal complex—the persistent tachycardia, the dilated pupils, and the moderately prominent eyes. Read's formula, which is considered to be a reliable inference of the basal metabolism, was in this patient slightly raised above the normal figure, and, consequently, it seems justifiable to conclude that the condition was one of congenital hyperpiesia of endocrine origin.

In right-sided hemiplegia, when the speech centre is involved, the aphasia may be complete except for "automatic speech," which may be the first hint of the returning function. In this connexion Kinnier Wilson relates how a patient, on witnessing the spectacle of a Zeppelin in flames, exclaimed "Hallelujah," and then lapsed into a silence as complete as before. In the case under discussion the words "I see" occurred repeatedly after the initial stroke, and subsequently, when speech was lost again. It may well be that the words were occasioned often during her avocation as a school mistress, and that, becoming spontaneous by constant use, they formed the whole extent of her expletives, and at times after her stroke, the sole intact connexion between her speech centre and the exterior.

I wish to thank Dr. Browning Alexander for his permission to publish this case, and Dr. Trounce for his report on the previous history of the family.

A CASE OF OLD-STANDING TUBERCULOUS KIDNEY.

BY

J. J. CONYBEARE, *M.C.*, M.D., F.R.C.P.,

ASSISTANT PHYSICIAN, GUY'S HOSPITAL.

THE case here recorded is of interest as showing that even advanced tuberculous changes in the kidney are compatible with prolonged life and comparative good health.

A man, aged 47, was admitted to Guy's Hospital in June, 1930. A brother had died from consumption at the age of 21; the patient lived in the same house with him during most of his illness. At the age of 18 the patient noticed that his urine was turbid, and he consulted the late Professor Julius Dreschfeld in Manchester, who made a diagnosis of tuberculous kidney. For some years the patient was kept under observation, and on several occasions had attacks of haematuria, often severe. At this time he had occasional fever and urinary symptoms such as frequency, but his general health remained sufficiently good for him to work for engineering examinations, and by about the age of 21 he was quite fit, apart from some frequency of micturition and occasional burning sensations in the region of the bladder. From this time until the outbreak of war he led an active life as a civil engineer; in 1914 he joined the Royal Engineers and went to France, serving in a Field Company.

In 1915, while on active service, he passed a few very minute stones, but did not have to report sick. In 1916, while still in France, he had a severe attack of pain in the bladder, and passed very large quantities of pus in the urine. He was invalided to England, and suprapubic cystotomy was performed in a military hospital, but no stones were discovered. The wound healed satisfactorily; the patient made an apparently complete recovery, and was able to return to active service in France in 1917. While on service he was exposed to conditions of great hardship; after six months his symptoms recurred and he was again invalided home. With medical treatment and a vaccine he again recovered completely, and was able to join the Royal Air Force in 1918. After the war he led an active life as an engineer and lived many years in the East. During this period his general health remained good and he put on a great deal of weight, eventually reaching close on 20 st. From time to time there was pyuria and slight frequency.

On May 1st, 1930, he suddenly became very ill; the urine became scanty and extremely purulent, and there was practically anuria for four days. The temperature was high—up to 101°—with severe diarrhoea and vomiting. With transient periods of improvement his illness lasted for six weeks, and he was often thought to be moribund; on several occasions he had severe rigors with high fever. Until he was transferred to Guy's Hospital there were no facilities for investigation, but clinically now was considered to be uraemic, possibly as a result of calculous -ria

On admission to Guy's Hospital the temperature was 102°, and the urine contained much pus, *B. coli* and streptococci being recovered. The blood urea was 110 mg. per cent., but the patient was passing fair quantities of urine and the vomiting was no longer severe. He was given large quantities of fluid with full doses of potassium citrate. On physical examination he was still well covered, though he stated that he had lost 6 st. in weight. His systolic blood pressure was 105 mm. Hg, but pulmonary emphysema made it impossible to discover the size of the heart. On rectal examination the prostate was found to be moderately enlarged; it felt as hard as a stone.

After a few days in hospital he had recovered sufficiently to enable an *x*-ray examination of the urinary tract to be undertaken. The films revealed the remarkable condition shown in Figs. 1 and 2. Practically the whole of the left loin was filled

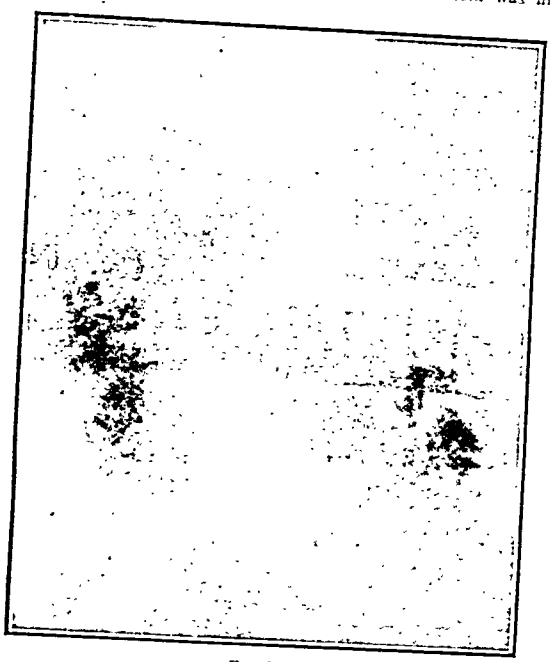

FIG. 1.

by an enormous shadow, which roughly conformed to the shape of the kidney. The outline of the left ureter could also be seen as an opaque line extending down to the bladder. In the *x*-ray plate of the pelvis (Fig. 2) the prostate appeared as a dense opacity. Several mobile opacities were seen near the hilum of the left kidney, but these were shown to be calcified mesenteric glands and not stones.

A few days later the patient was cystoscoped. The bladder was small, but there was no difficulty in the passage of the instrument in spite of the calcified prostate. The left ureteric orifice could not be seen, but there was much cystitis, and the right ureteric orifice was ulcerated. After intravenous injection of methyl violet the dye did not appear from the right ureter for fourteen minutes.

The patient remained in hospital for about three weeks and made a steady recovery. The blood urea dropped from 110 mg. on admission to 50 mg. on discharge. Good amounts of urine were passed throughout, and the urine became practically clear.

This case is of interest as an example of abortive attempts at healing by a tuberculous kidney. The whole of the organ appears to have become replaced by a tuberculous pyonephrosis of enormous dimensions, and the tuberculous caseous material has become so infiltrated with lime salts as to produce a dense shadow to *x* rays. The ureter of the affected kidney has never been permanently occluded, as evidenced by the shadows in the *x*-ray film. Inquiries from the patient elicited the fact that from time to time he experienced a sensation "as if a tap had been turned off in the bladder." This was followed by the passage from the urethra of cretaceous material, which the patient described as like tooth-paste in colour and consistency. It would appear, therefore, that from time to time some of the caseous material from the kidney was passed in the urine. No tubercle bacilli could be found, and probably the tuberculous process is completely arrested. The acute symptoms with which the patient started his recent illness were presumably due to an exacerbation of his chronic urinary infection preventing satisfactory functioning of his right kidney.

The case tends to show that, even when there is high resistance to tuberculous infection, involvement of the kidney may lead to serious consequences as the result of secondary urinary infection; it emphasizes the importance of nephrectomy whenever the condition of the other kidney warrants this step being taken. Undoubtedly a tuberculous kidney may be completely transformed into an innocuous calcareous mass, but such spontaneous cure is probably

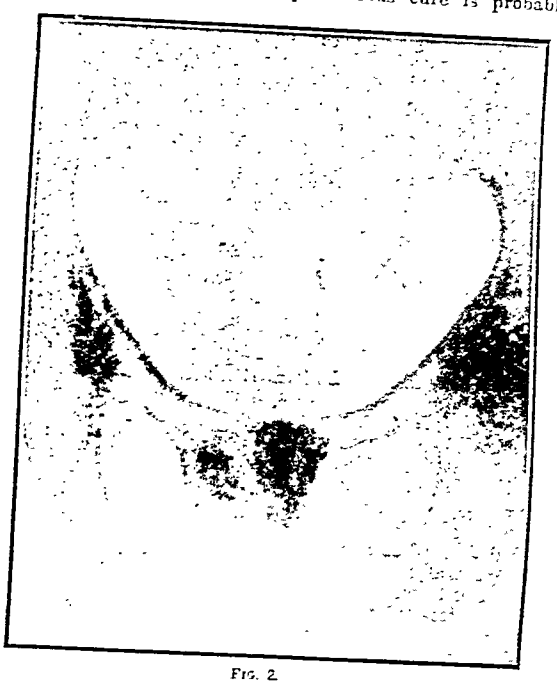

FIG. 2.

very rare. The only example I have met of such a condition was in a woman, nearly 80 years old, who was killed in an accident. One kidney was a hard calcareous mass about two inches in length; the other kidney showed much hypertrophy.

HAEMORRHAGIC DRY BRONCHIECTASIS.

BY

A. J. SCOTT PINCHIN, M.D., F.R.C.P.,

PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, VICTORIA PARK, THE WEST LONDON HOSPITAL, AND THE HAMPSTEAD GENERAL HOSPITAL;

AND

H. V. MORLOCK, *M.C.*, M.D., M.R.C.P.,

PHYSICIAN TO OUT-PATIENTS, THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, VICTORIA PARK; AND ASSISTANT PHYSICIAN TO THE HAMPSTEAD GENERAL HOSPITAL AND THE MILLER GENERAL HOSPITAL.

THE importance of the pathological condition here described lies in the tendency that arises, on account of the haemoptysis (which is the main symptom) to group all these cases as tuberculous. To diagnose a case as tuberculous which is not, is to do the patient a great disservice; it may completely alter his prospects in life. There is no doubt that the diagnosis of tuberculosis has generally become more accurate during the past twenty years; it has ceased to be the lumber-heap of unclassified conditions it was wont to be. In order that this improvement may continue it is opportune to lay stress on this not infrequent pitfall in diagnosis.

CASE V.

A man, aged 50, twenty years previously had had a subphrenic abscess and an empyema, which was drained. Since then he had worked as a stevedore. Two years ago there was a haemoptysis of 10 oz., and eighteen months later one of 5 oz. When seen in the out-patient department he was having a haemoptysis of 10 oz.

CASE V.—After lipiodol.

The patient was a robust, healthy man, with no physical signs except for a few added sounds round the empyema scar. A skiagram before lipiodol injection showed no abnormality, but after the lipiodol injection a cavity 1½ in. by 3 in. was demonstrated behind the cardiac shadow.

CASE VI.

A girl, aged 17, had had pertussis when 4 years old, and since then bronchitis. During the last four years there had been repeated haemoptysis, and she had twice been in a sanatorium.

Her general condition was fair, but there was dullness, with added sounds at the left base. A skiagram showed the triangular shadow behind the heart, and lipiodol injection demonstrated bronchiectasis within this shadow.

CASE VII.

A woman, aged 31, had had pneumonia fourteen years previously, with an empyema which had been treated by open drainage. She had never been ill since, until one year ago there was a haemoptysis of 1 oz. Since then she had occasionally coughed up half an ounce of sputum in the day.

She was found in very good condition on examination, and had just gone through her third pregnancy. There were physical signs of fibrosis at the left base, but no clubbing. The skiagram was suggestive of fibrosis at the left base, and lipiodol demonstrated cylindrical bronchiectasis.

CASE VIII.

A woman, aged 40, had been quite well until one month before attending the out-patient department, when she had a haemoptysis of 10 oz., since when occasional expectoration had occurred.

She was a stoutish woman, with no clubbing, but there were definite signs suggesting bronchiectasis at the right base. Lipiodol injection showed a well-marked bronchiectasis.

CASE IX.

A woman, aged 23, had had influenza one year previously. During the three months before she was seen in the out-patient department there had been repeated small haemoptyses. There was a small amount of sputum.

The general condition was fair, but there was an impaired note and diminished breath sounds at the right upper lobe. The sputum examination had been repeatedly negative for tubercle bacilli. The skiagram suggested that there was a small cavity in the region affected, and lipiodol demonstrated dilated bronchi. Six months later the patient had another haemoptysis of 10 oz., but the general condition remained unaltered.

In all the above cases the sputum had been examined for tubercle bacilli, and found negative.

In 1924 Bezançon, Weil, Azanlay, and Bernard[3] recorded two such cases under the heading of "Sèche hémoptorique de la dilatation des bronchis." In 1927 Reinberg reported six more cases. In 1929 Burrell and Trail[4] briefly described one case. The patient of Burrell and Trail and two of Reinberg's patients had been in sanatoriums, and one of ours had been similarly treated. Two others had been suspected of being tuberculous; one had attended a tuberculosis dispensary for twelve years.

The haemoptysis is usually copious, from 3 to 15 oz. Such a large haemoptysis is not commonly seen in an initial haemoptysis in pulmonary tuberculosis; in association with this there is an absence of constitutional signs. The haemorrhages are usually recurrent, and one of our own patients has worked as a domestic servant for the previous seven years, having large haemorrhages every few months, and, except for a day or two's rest on each occasion, continuing her duties. Cases ii, iv, v, vii, viii, and ix were treated in the out-patient department during the period they were having haemorrhages. The physical signs are indefinite, and it is often impossible to detect anything more than a slight degree of fibrosis, the interpretation of the signs being rendered more difficult by the fact that often there has been an empyema or pneumonia in the past on that side.

The majority of patients give a history of a previous inflammatory condition of the lung—7 of the cases we record here (3 empyemata), and 5 out of 6 of Reinberg's cases. The history of a previous acute inflammatory condition of the lung is in keeping with the usual etiology of bronchiectasis, and one might reasonably assume the progression of the disease, through a symptomless dry bronchiectasis to the later stage when the bronchiectatic dilatations become infected and begin to secrete, as being the usual evolution of the disease in cases arising after pneumonia and such conditions. One of the Bezançon cases was watched from the dry to the moist stage, and doubtless now that the condition is recognized a follow-up of cases in the future will show this to be a common sequel.

The interval between the acute illness and the haemorrhage which brought the patient for medical advice is instructive, twenty, fourteen, eight, two (6 cases), and one year elapsing in some of our cases, in Reinberg's cases the longest period was twenty-eight years and the shortest five years. We feel confident that many practitioners will remember one or more cases which probably came in this category, and that the condition must be by no means uncommon.

Treatment.

In none of the cases reported in the literature, nor in our cases reported here, has any radical measure been undertaken to deal with the disease, because all the patients have been in good condition, and one has hesitated to suggest artificial pneumothorax, phrenic avulsion, or thoracoplasty, these methods being the only available ones for dealing with the disease.

One of us had a phrenic avulsion performed on a case (not in the series) in which an artificial pneumothorax could not be induced, on account of severe haemoptysis, with an apparently good result; if the haemoptysis threatens life (Devic and Berthier[5] reported four fatal cases) one of these measures would have to be undertaken. It is, however, a point for consideration whether one should conduct some treatment to avoid infection of the cavities; this question can only be solved by watching the course of the cases now that we have recognized the condition, since it is seen that many of them escape infection for years.

The *x*-ray appearances of all such cases are of interest; often the condition is not distinguishable at all without the use of lipiodol. Space prevents us giving more than nine examples.

Conclusion.

Cases presenting the symptom of haemoptysis, when the physical signs are inconclusive, and where skiagrams show no definite evidence of pulmonary tuberculosis, should be subjected to the investigation of a lipiodol injection of the bronchial tree, and subsequent radiology.

Our thanks are due to Dr. Sparks and Dr. Wylie for the radiograms reproduced.

The cases that originally did badly show deplorable results later, whereas those in which there was an immediate response now give far superior results. The difference is so marked that it can be used for purposes of prognosis; it seems reasonable to infer that a patient who does badly during and immediately after antigen treatment has a bad prognosis, whereas those who improve after the treatment have a much better chance of ultimate survival.

The after-history of the groups testifies to the accuracy of the original clinical work, and it is only just to record my deep obligation to all the Salford practitioners who sent patients and reported upon them.

The accuracy with which the groups were originally formed lends increased value to the clinical opinions given on the same cases now, but it is recognized that there is no agreement among clinicians as regards data useful for prognosis; so the percentage of those now alive has, therefore, been given, for at least there can be no question as to the living and the dead. It will be seen that the proportion of survival after two to three years is three times as high in the group that responded immediately to treatment. It may be added that in the case of the 32 patients who remain improved the benefit is such that 19 are at work without ill effect; the majority of the remainder are women doing housework, which is difficult to assess. In any future series the obviously hopeless cases would be refused treatment, and the results no doubt would show a higher proportion of success.

Attention was concentrated upon pulmonary tuberculosis because it constitutes the largest section of the disease, and has a bad prognosis as it is usually treated. Other forms of tuberculosis have been investigated, and it has been found that the most spectacular results were obtained in young adults with tuberculous enteritis but with no clinical evidence of pulmonary involvement. In this class the antigen rapidly brought down the temperature, and the patients usually gained 30 or 40 pounds in weight during the treatment; all clinical signs cleared up, and the patients remain apparently cured. The utility of the antigen is necessarily limited by the comparative rarity of the condition.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

TUBERCULOUS ADENITIS WITH DERMAL BULLAE.

THE following case appears to be worthy of record in view of the unusual occurrence of tubercle bacilli.

A plumber, aged 41, was admitted to the West Riding Sanatorium on October 1st, 1929; he had been healthy until four years previously, when the illness commenced. A brother had died of pulmonary tuberculosis.

On the right side of the neck above the clavicle was a diffuse, fairly tense, tender, and fluctuating swelling; in the posterior part of this could be felt deeply some harder masses of obviously enlarged and matted cervical glands. There was in this region the scar of an old gland operation. The skin over the swelling was quite healthy, but below the angle of the jaw on each side was an ulcerated area similar to the ones to be described. The swelling had commenced a month before admission, but the ulceration was of much longer duration.

The left forearm and hand were swollen; the skin was extensively and irregularly involved in a sloughy, ulcerative condition, particularly in the interdigital clefts and on the back of the hand. On the forearm about the elbow were three clear-cut shallow ulcers, one to two inches in diameter, with a low granulating surface. Purulent subcuticular bullae had formed over the rest of the forearm; some of these had ruptured, leaving a sloughy base, this being apparently the early stage of the more clearly marked ulcers previously mentioned. The appearance was that of a pyogenic infection of the skin with little inflammatory reaction. Fresh pustules appeared, containing greenish pus and having no inflammatory areola, and these also underwent a similar breaking down. The arm was not examined radiologically, but there did not seem to be any involvement of the bones. This condition had commenced about four years before.

A similar condition commencing at the same time on the left hip had cleared up; more recently, two small ulcers in the region of the great trochanter had again appeared, but presented no special features. There was no indication of pulmonary tuberculosis, and the sputum, when obtained, was found to be negative for the tubercle bacillus.

Three days after admission the cervical swelling was explored in its lower part, and 34 c.cm. of thick, greenish pus with a foul odour were aspirated. A smear of this pus stained by Ziehl-Neelsen's method showed enormous numbers of typical tubercle bacilli and polymorphonuclear leucocytes, many of which contained clumps of the bacilli. Rather less than three weeks later 52 c.cm. of pus were withdrawn, and 8 c.cm. of Calot's fluid were injected. Three days later still the abscess was found to be very tense; the pus had suddenly made its way to the skin at two points close together in the upper part of the swelling, the appearance being as if two large deep-seated pustules had formed. Despite the aspiration of another 65 c.cm. of purulent fluid the abscess burst. This pointing and bursting took place with an entire absence of inflammatory reaction, which otherwise might have suggested a secondary infection of the abscess. Smears of pus from an unruptured pustule on the forearm also contained the tubercle bacillus, although in much smaller number than in the case of the pus from the cervical abscess.

The patient's general condition was poor from the outset; his temperature was high and swinging (100°-103°), with a pulse persistently over 110 at night, and he showed evidence of grave toxaemia. He gradually sank and died on December 7th.

This case seems to be of interest in three particulars.

1. The presence of the tubercle bacillus in the pus from the cervical abscess in such enormous numbers is very unusual; the organism is rarely to be found at all in the pus from a tuberculous abscess.

2. The rapid manner in which the abscess filled up and finally burst, with no preliminary warning changes in the skin, was surprising.

3. The extensive and atypical lesions on the forearm simulated a low-grade pyogenic infection; they were, however, proved to be tuberculous by the finding of the organism in the pus from an unruptured bulla. No doubt the lesions were later contaminated by pyogenic organisms, but the initial lesion would appear to have been tuberculous.

I am indebted to the medical superintendent, Dr. Thompson Campbell, for permission to report on this case.

Assistant R.M.O., West Riding Sanatorium.

CONGENITAL UMBILICAL HERNIA OF LIVER AND BOWEL.

THE rarity of the following condition entitles it, perhaps, to publication.

A baby, two weeks premature, was brought to the Bradford Children's Hospital thirteen hours after normal birth, the mother had had two other healthy children. It appeared healthy and well developed, except that the recti muscles were separated for one and three-quarter inches at the umbilicus, through which there was an expansion of the base of the umbilical cord, forming a thin transparent sac about the size of an orange. The sac was very tense and elastic, and it was obvious that the contents consisted of at least two different structures; the larger appeared dark red and opaque, the smaller part being translucent. The umbilical cord was continuous from the lower aspect of the expansion as a normal cord.

Under chloroform and ether anaesthesia an attempt was made to reduce the contents of the sac, but this was unsuccessful; the part of the cord forming the wall of the sac was then incised, and the sac was opened. Part of the contents was found to consist of a dark red, almost spherical, mass with paler areas; it resembled liver substance and was about the size of a small orange. The wall of the sac was adherent to the mass along its mid-line on the anterior surface, and had to be dissected off. There was also small bowel in the sac, which was returned to the abdomen; the red mass was traced upwards and appeared to be continuous with the liver. Since the child's condition was poor, it was not considered advisable to explore further. Owing to the smallness of the orifice, compared with the hernia, the mass was with difficulty returned to the abdominal cavity. The excess of the sac and the cord were excised, and the abdomen was closed. The child only survived three and a half hours after the operation.

The mass was found to consist of liver representing more than half of that organ; at its extremity was the ligamentum teres. The line along which it had been dissected from the sac was its anterior peritoneal reflexion. On its lower surface was the gall-bladder, practically concealed in liver substance, and three-quarters of the bile duct. No other developmental abnormalities were found.

I am indebted to Mr. Gordon D. Latimer, assistant surgeon to the hospital, for permission to record the case.

Bradford.

CLINICAL OBSTETRICS.

PROFESSOR PAUL T. HARPER'S *Clinical Obstetrics*[3] is a comprehensive and sound survey of the subject it approaches, but there are now so many such works that one looks in vain for fresh information in each new volume. Without depreciating the many excellent textbooks on midwifery which are the work of single authors, we cannot but feel that there is now likely to be more value in the work of several collaborators, where the experience is wider and merely personal dicta are less frequent. The value of the present work is somewhat lessened by the illustrations, which are often far from clear, and in our opinion are for the most part executed in a style hardly suitable for the purpose. The chapter on placenta praevia is excellent and full, though its arrangement might have been clearer; and it is surprising to find no reference to the use of Willett's forceps, which in this country have been proved to be of inestimable value in dealing with this condition. Professor Harper also recommends the injection subcutaneously of alpha lobelin in cases of serious asphyxia neonatorum; others have found its action to be quicker and more efficacious if injected into the umbilical vein. In the chapter on version we looked for an opinion on the methods of Potter, who performs version in all cases and always delivers by the breech. Professor Harper is only half-hearted in his disapproval of this practice. There can be no doubt that the technique of version and breech delivery has improved immensely during the last few years, but many obstetricians still believe that it is a method to be reserved for cases of emergency. It is usually the task of the surgeon to assist and not to reorganize the methods of nature.

RADIOGRAPHIC TECHNIQUE.

Roentgenographic Technique[4] is the title of an elaborate book by Dr. DARMON ARTELLE RHINEHART, restricted to this side of radiological practice. The author claims that all books on this subject already published are either out of date or else incomplete in some particular; and, to quote from the preface:

> "By introducing a series of experiments for determining the operating peculiarities of each Roentgen-ray machine, by providing a simple experimental method of measuring the Roentgen-ray output of each equipment, and by basing exposure on the thickness and roentgenographic density of parts of the body, a method of perfecting a roentgenographic technique has been devised that may be used in any Roentgen-ray laboratory, irrespective of the apparatus it may contain."

When we come to examine this book in detail we find that its twenty chapters run to some three hundred and seventy pages, together with a comprehensive index. There are also numerous illustrations, diagrams, and charts. Each chapter has a short bibliography attached bearing on its subject-matter, the articles referred to being almost entirely drawn from American journals. The opening chapters deal shortly with electricity and electric currents, *x*-ray machines, tubes, dangers, the nature of *x* rays, intensifying screens, the Potter-Bucky diaphragm, and the dark room and development of films. The author follows these with a description of some ten experiments, which might be said to be the subject-matter of his book. The first three of these include the directions for making a working calibration of any *x*-ray machine producing rectified current, irrespective of type. The following three experiments are included to illustrate and explain the laws which govern exposures. A basic roentgen technique is explained, and followed by descriptions of a few more points which bear on the subject. It is all very interesting, and it is obvious that the author has put in an enormous amount of time and work in elaborating his technique, but it is a fair criticism to say that it is by no means so simple as is suggested, and it appears to be very doubtful if it will come into general use either in hospital or in private *x*-ray clinics.

Further advanced experiments follow, the objects of which are to teach a method of photographically measuring the *x*-ray output of an *x*-ray machine, to make a determination of the relationship between thickness and voltage, and to prepare a thickness-voltage chart. The latter part of this book deals, in about two hundred pages, with a detailed description of the technique required for obtaining radiographs of the various regions of the human body. Each part of the anatomy is treated separately, and numerous photographs as well as radiographs illustrate the text. We have nothing but praise for this portion of the book; the illustrations are excellent, and are so arranged as to show quite clearly the exact position of the part under examination and its relationship to the *x*-ray tube and to the film, whilst alongside of this is a reproduction of the resulting radiograph. We are able to congratulate the author on a masterly production.

DIATHERMY IN OTO-LARYNGOLOGY.

THE latest addition to the Anglo-French Library of Medical and Biological Science, produced under the general editorship of Drs. Crookshank and Cruchet, is *Diathermy, Medical and Surgical, in Oto-Laryngology*,[5] by Dr. DAN MCKENZIE. This belongs to the more practical side of the collection, but it exhibits a happy choice wherein practice follows a strictly scientific application of the physical properties of electrical currents. The editors therefore merit a word of congratulation as well as the author.

The general principles and application of diathermy have become tolerably familiar during the last twenty years, as its use has become general. The field of medical diathermy is still extending in various directions, but surgical diathermy has proved particularly acceptable to laryngologists. Dr. Dan McKenzie shows, however, that medical diathermy also is a valuable agent in otology and laryngology. Patients with laryngitis, coryza, eczema, furunculosis, and tinnitus may derive benefit from this treatment, and the author sets out fully the indications and methods of application. The use of surgical diathermy falls into two main divisions—for non-malignant conditions and for cancer. It can be used for the gradual destruction of tonsils as an alternative to excision, for the removal of innocent tumours, and for the treatment of hyperplastic laryngitis and lupus. Its chief use, however, has always been for the treatment of cancer, and a complete account is given of what can be accomplished and how the best results are to be obtained. The pharynx and tongue are the principal sites, but its possibilities in other places are also explored. The relative merits of excision, radium, and diathermy are assessed briefly, and it is also shown how they can be combined with advantage. A sufficient description of the underlying principles is given, with an account of the different ways in which the electric current can act through the medium of the various instruments.

The book has been written from an extensive clinical experience, and is far more than a compilation. It collects, however, under one cover much information which otherwise could only be acquired from scattered sources, so that it has a double interest for the laryngologist, and provides him with many additional therapeutic resources.

INFANT NUTRITION.

DR. W. MCKIM MARRIOTT'S contributions to the study of paediatrics are so well known that the appearance of a textbook by him on *Infant Nutrition*[6] is most welcome. He has written a fine comprehensive volume which begins with chapters on metabolism, the nutritional requirements of infants, digestion in infancy, and so passes by logical steps to the actual feeding details. Dr. Marriott's interest in acid milks might well have resulted in a one-sided exposition of artificial feeding, but this is not so, and the case for lactic acid milk is presented so fairly and soberly

AN OUTBREAK OF MINOR SMALL-POX IN LEICESTERSHIRE.

THE prevalence of minor small-pox in Leicestershire during the past twelve months has afforded an excellent opportunity of observing its clinical and epidemiological features. It is hoped that, in the absence of a comprehensive literature, the following remarks concerning the type of the disease will prove of some help to those who may, without previous experience, be confronted with a case, or perhaps with a group of cases. Our experience has been that cases occurring for the first time in any one locality usually pass unrecognized.

GENERAL CHARACTERISTICS OF THE EARLY STAGE.

Incubation.—The incubation period is exceedingly variable. From my records of cases the commonest incubation period is approximately fourteen days. Two cases have occurred, however, in which the incubation period was only ten days, while in another case its duration was twenty-one days.

Infectivity.—The infectivity of minor small-pox is exceedingly interesting when compared with that of true small-pox. The infective potency appears to be very low. In several instances single cases have been observed in large unvaccinated households, the remainder of the family, though freely exposed during the period of highest infectivity—that is, while the rash is coming out—having all escaped. The most, and possibly the only, infectious period of minor small-pox is while the rash is developing; from our experience minor small-pox does not appear to be infectious during the prodromal stage, or after the rash has ceased to erupt.

Extension of the Infection.—The commonest line of spread appears to be among persons sharing the same bedroom, although one unvaccinated girl escaped infection in these circumstances. Another common mode of extension is courting by young couples; infection regularly spreads among these people if vaccination is refused, and is frequently responsible for a fresh outbreak in a new neighbourhood. A definite case of propagation by fomites has not come under our observation, though cases have been reported by some authorities.

Prodromal Stage.—This is usually the only period of the disease in which the patient complains. The sudden onset, great prostration, and rapid recovery before the appearance of the rash are the most significant features of this stage. About 90 per cent. of the patients suffer for a few days before the development of the rash; the remaining 10 per cent. may present no prodromal symptoms whatsoever, or on close interrogation give a history of malaise and headache, lasting several hours, about four days before the appearance of the eruption. The prodromal stage usually continues for forty-eight hours up to five days, the average being four days. The symptoms in order of frequency are frontal headache, lethargy and malaise, backache, feverishness with perspiration, vague pains in the legs, nausea with occasional vomiting (the latter being invariably present in children), and hoarseness. The common clinical history is as follows. A man ceases work at midday with frontal headache and malaise. The next day is spent in bed, with headache, fever, giddiness, and generalized pains—a typical clinical picture of influenza. On the following day he feels better, gets up, and returns to work on the fourth or fifth day, the rash appearing on one of the two days. On no occasion has a prodromal rash been seen, although an erythema sometimes occurs on the flanks of fair people during the prodromal stage.

THE RASH.

The rash begins as small macules, which rapidly become papules within twenty-four hours. The papules are circular, and turn into turbid vesicles on the second or third day of the eruption. These vesicles, which are again invariably circular (the most important point in diagnosis), enlarge on the fourth or fifth day and become typically pustular. Throughout the whole evolution of the rash the eruption is always circular. The lesions are deeply situated, and may give a shotty feel; umbilication occurs only in the bigger pustules. The size of the lesions is variable; as a whole, they are considerably smaller than those presented in true small pox, measuring from one-tenth to two fifths of an inch in diameter. In minor small-pox the eruption frequently occurs in crops, and so closely resembles chicken-pox; the crops may appear any time during the first week.

The distribution of the rash is of extreme importance. The eruption usually begins round the lower edges of the cartilages of the nose, along the supraorbital ridges, and over the malar prominences. The concentration of the rash on the face is variable, and only three or four lesions may occur; sometimes several hundred are present, but most commonly the papules number from ten to thirty. The rash next develops on the shoulders and back, a common site being along the vertebral border of the scapulae. It is most important to note the presence of the eruption on the forearms. Though the papules appear more densely on the extensor surface, they are usually found over the flexor muscles and over the brachioradialis. An invaluable aid in diagnosis is to find papules on the wrist and hand. In this situation the lesions are commonly seen in the palm and on the dorsum of the fingers and hand; other favourite sites are the thenar eminence, around callosities, and over sites of irritation. The upper arm is less densely infected than the forearm.

The appearance of the rash on the lower extremities somewhat resembles that on the upper extremities. Papules are usually found on the buttocks. The lateral aspects of the knees are sites of relative density. The soles and malleoli are also sites which are frequently affected.

The occurrence of a palate rash is sometimes observed and papules may be occasionally seen at the junction of the hard and soft palates at the very onset of the eruption; this is of great assistance in diagnosis. On one occasion a contact whose symptoms had been similar to those of the prodromal stage of small pox was immediately isolated as suffering from small pox on the development of a papule on the palate and a macule on the face.

As in true small pox, the occurrence of the eruption on the abdomen, in the axillae, and in the folds of the groin is very rarely seen. The reason for this is that these situations are less exposed to irritation than are such places as the extensor surface of the forearms and the lateral aspects of the knees; in these areas the rash is usually concentrated. On two occasions, however, in children under the age of 12 months, we have seen profuse eruptions of small-pox papules in the groins, on the perineum, and over the lower abdomen. The natural explanation is that these situations are exposed to considerable irritation in infants.

A noteworthy point has been the sudden way in which the incidence of small pox decreased during the month of June. There has also been a definite modification in the eruption, which on three occasions aborted in the papular stage; to use a colleague's definition, "it almost appears to have reached vanishing point."

Several cases of small-pox *sine eruptione* occurred. One unvaccinated male adult presented a typical syndrome of prodromal symptoms fifteen days after his sister had been removed to hospital suffering from small pox. This patient complained of lethargy, frontal headaches, severe perspiration, and pains in the back. A close watch was maintained but no eruption occurred.

DIFFERENTIAL DIAGNOSIS.

Apart from an epidemic, or at least some preceding cases, the prodromal stage of small pox is hardly ever recognized. In an epidemic it is frequently confused with influenza, lumbago, mild gastro-intestinal disturbances associated with slight fever, and toxaemia. Recognition of the prodromal stage is a signal for the prompt vaccination of contacts where possible, and for the removal of the patient to hospital when the rash appears.

The small pox rash is most frequently confused with acne, chicken pox, and Bockhart's impetigo. Apart from a chicken-pox epidemic occurring simultaneously, the most common and difficult point arising in diagnosis is the differentiation of minor small-pox from acne in the pustular stage. In such a case the eruption is discrete and circular, often on the face and back, and so resembles minor small-pox in the early pustular stage; on further investigation of the distribution, however, no pustules are found on the extremities, there is no history of prodromal symptoms, excessive scarring of old acne is present, and there is often the history of similar pustules for some weeks.

Difficulty is presented in distinguishing severe chicken pox from minor small-pox in young adults. This primarily arises before the appearance of the eruption, severe chicken pox being frequently preceded by symptoms resembling those of the prodromal stage of minor small pox, and lasting up to forty-eight hours. A woman, aged 28, who had had prodromal symptoms, was covered with pocks over the face, back, and arms—a similar distribution to that of small pox. On close examination with a lens, however, every pustule was seen to be slightly irregular in outline, not one in many hundreds being found uniformly circular, as is the almost invariable rule in minor small pox. The lesions presented a knotty feel on the forearms, a characteristic often seen in chicken pox as well as in small pox. Another case of chicken pox recently observed presented no less than six lesions on the plantar surface of the right foot and eight on the dorsum. These pustules occurred in an otherwise typical but fairly severe case of chicken-pox, diagnosed by the polymorphic appearance of the eruption and its distribution.

VACCINATION.

In a total of 625 patients suffering from small-pox there has not been a single one who has been vaccinated within thirty-seven years (except contacts vaccinated late after exposure to the disease). This is a most instructive and interesting observation. In order to discount its value it has been suggested that in Leicestershire, being the county with the lowest percentage of

British Medical Journal.

SATURDAY, AUGUST 30TH, 1930.

THE PRESIDENTIAL ADDRESS.

THE welcome which the British Medical Association is now receiving in Canada, and especially in Winnipeg, is fully expressed in the presidential address by Professor Harvey Smith, which we have the pleasure of printing this week. The keynote of that address is the "earnest hope that this meeting in Canada will serve to strengthen between the Dominion, the Mother Country, and the various other units of the Empire the ties of scientific fellowship, fraternal good will, and patriotic unity," together with an acknowledgement of the "mutual understanding and cordiality" existing between those units and the United States of America. The President declares that "the bonds of Empire are growing stronger, and there is increasing evidence that Canada shares with the Mother Country a common outlook and a common destiny," and that, moreover, "Canada, in growing strong and prosperous and confident, has become increasingly capable of fulfilling the great duty of interpreting the British Empire to the United States."

A gathering which can in some degree help to forward these wide purposes, and is designed to advance them greatly in the sphere of medicine, is indeed a memorable one. The previous meetings of the British Medical Association in Canada—that in Montreal in 1897 and that in Toronto in 1906—were remarkable, but the present meeting is even more so. As the President tells us, "a prophecy made in the 1860's, before the Red became a Canadian river, and when Western Canada was a wilderness, that such a gathering as the present would be possible on the banks of the Red in 1930," would have been regarded as quite visionary. Yet so rapid has been the development that "we have still with us in Winnipeg several residents who are survivors from the era before Manitoba entered the Confederation as the fifth of the nine provinces of to-day. They remember when there was still to be seen crossing the area now within the city an old trail along which the buffalo used to travel to a drinking-place on the bank of the Red River. They remember the festival known as the White Dog Feast, for which the Indians used to assemble every summer. That festival was held for the last time on Point Douglas, which is within the city of Winnipeg, in June, 1873. In performing the elaborate ceremonial at that festival the medicine men officiated, but more as priests than as physicians." There is thus a reminder of the progress of medicine as well as of the development of Canada. Professor Harvey Smith recalls that the first hospital in Canada was the Hôtel-Dieu in Quebec, founded in 1639.

It is natural to think first of the advance of medicine as a science and as an art or craft, and of the education by means of which this science and art has been extended and made known. In these respects the President tells us that "Canada regards Great Britain as its fountain head." It has to be confessed that, if not in the material and in the excellence, yet in the organization of its post-graduate teaching, this country has compared unfavourably with certain centres on the continent of Europe and in the United States, and that the President's reproach in this regard is justified. There has been much, perhaps unavoidable, delay in making good these deficiencies of organization; but it may now be confidently expected that in the early future there will be in London, by the co-operation of the Government, the London County Council, the University of London, and the clinical and teaching staffs of the schools of medicine, well-organized post-graduate facilities second to none elsewhere. Practitioners from Canada, as well as those from the other oversea Dominions and elsewhere, may rest assured that every endeavour will be made to meet their needs and their conveniences, and to make them welcome.

Professor Harvey Smith has some wise words to say on medicine in its more social aspects. He tells us that "the economic organization of medicine has not kept pace with its scientific progress," and says: "Conditions of practice have been changed vitally, in method and in outlook, by the prodigious growth in medical knowledge, and the keener appreciation, both of the public and of our profession, of the right of citizens to good health and skilled medical care. . . . A prolific source of criticism and of dissatisfaction arises from the failure of our profession to provide competent service to the various sections of the community under a financial plan that will meet the needs of every class of citizen." He points out that if the medical profession does not itself make this provision the State will be driven to do so, and may do it on lines which the profession would not fully approve. He draws attention to certain movements in this direction in British Columbia, in Alberta, in Saskatchewan, and in other parts of the Dominion, and to the fact that "both the Canadian Medical Association and the Department of Pensions and National Health at Ottawa are making a study of medical care and its cost, with a view to submitting constructive recommendations at a later date." In his judgement there is only one possible solution—"voluntary health insurance, instituted, organized, and controlled by the medical profession, and widely applied," and he lays down the principle that "the field of public health must and should be the interest of Government, but private practice must remain in the hands of the individual physician if the public is to receive the highest and best type of medical care." He refers in this connexion both to the National Health Insurance Acts of this country and to the proposals for a general medical service for the nation recently adopted by the British Medical Association.

It is clear that the problems to which these observations refer, and which these Acts and proposals are intended to meet, though fundamentally similar, are not identical in the two countries. Nevertheless, experience in the one should not be without its lessons for the other. The differences are evident in that section of the address in which the President touches on the question of specialism in medicine and the desirability of its statutory definition and regulation. The need for such regulation is not felt in this country to the same extent or in the same way as in Canada; nor would the profession here, in present conditions, view with approval such legislation with regard thereto as has recently been enacted in the Province of Alberta, and which the President himself regards, from his point of view and in the circumstances of Western Canada, as an "excellent lead." But "the science and the art of medicine are not circumscribed by any geographical boundaries. They belong to humanity." There is no doubt that the Annual Meeting of the British Medical Association in Winnipeg

attention during this meeting of the British Association are: some effects of low-frequency vibration on body and mind; outstanding features of the "circular type" of character; the relation between thought and fantasy in young children; the mental processes involved in learning a foreign language; the place of industrial psychology in a university city; psychological factors in peripheral vision; the psycho-physics of desire, perseveration and the introvert; the interest to the psychologist of conditioned reflexes; and psychological analogues of the conditioned reflex. In the Chemical Section the presidential address will be delivered by Professor G. T. Morgan on "A State experiment in chemical research." A paper will be read by Sir William Pope, who will also take part in a discussion on the present position of the British dyestuff industry. A comprehensive discussion on chemotherapy will include the application of arsenicals to tropical medicine and the mechanism of their action. In the Zoological Section the presidential address will be delivered by Dr. W. T. Calman, who will consider the taxonomic outlook in zoology, and Professor F. A. E. Crew will read a paper on the effects of density on a mouse population. Other subjects to be dealt with in this Section include the phylogeny of the placenta, evolution of the primates; and the musculature for opening and closing the mouth in vertebrates. A wide choice of excursions has been arranged for delegates.

TREATMENT OF PNEUMONIA WITH VITAMIN A.

THE investigations of Mellanby and Green of the value of vitamin A as an anti-infective factor—above all, their application of the results obtained in the course of animal experiment to the treatment of a series of cases of puerperal sepsis—have naturally directed the attention of a number of observers to the possibility of treating other infections by the same agent. It may be recalled that in a paper published in the *British Medical Journal* of October 20th, 1928 (p. 691), Mellanby and Green recorded experiments by which they had shown that whereas animals fed on a vitamin A-free but otherwise adequate diet died from infective and pyogenic conditions, control animals receiving this accessory food factor remained in good health; animals which had developed infective lesions often recovered completely if they were given vitamin A abundantly and in good time. Applying these findings to human infections (*Journal*, June 1st, 1929, p. 984), they treated five cases of puerperal septicaemia due to *Streptococcus haemolyticus* (the organism in each case being isolated from the blood), and the result—namely, recovery in every case—was in such marked contrast to those previously obtained at the same hospital in the treatment of cases of puerperal septicaemia that there seemed good reason for believing that the recovery could be attributed to the treatment they had administered. An attempt to apply similar treatment to a series of cases of pneumonia in native mine labourers is recorded by Drs. S. Donaldson and J. Tasker in the *Proceedings of the Transvaal Mine Medical Officers' Association* for February and March, 1930. During the period August, 1929, to February, 1930, inclusive they treated 299 cases of uncomplicated lobar and bronchial pneumonia, adopting ordinary routine methods in 100 cases, treatment by means of ox liver in 99 cases, and treatment by means of concentrated vitamin A preparations in 100 cases. Patients were placed in one or other of these three groups strictly in rotation, and no attempt was made to select cases for treatment by any of the methods adopted. The administration of massive doses of vitamin A was maintained in each case for two days following the fall of temperature to normal, and in this series the case mortality was 8 per cent.; in the control cases treated by ordinary routine methods the mortality was 13 per cent.; and in the cases treated by ox liver it was 9.09 per cent. Very slight differences between the three groups were found in the average duration of supernormal temperature per case and in the average duration of persistence of physical signs, but there was a striking contrast between the incidence of cases showing delayed resolution in each group, the number in the control group being 17, in the liver group 7, and in the vitamin A preparations group 12. The authors of the paper admit freely that pneumonia is so varying in its clinical aspects and mortality that they would not be justified in drawing any far-reaching conclusions from their comparatively small series. They throw out, however, the interesting suggestion that if, as is probably the case with vitamin C, a depleted reserve in the body must be re-established before the massive doses of vitamin A can exercise a beneficial effect, it is possible that in a disease like pneumonia, rapid in onset and course, time is too limited for the necessary reserve to be built up, and very good results may therefore not be hoped for.

THE TRAFFIC IN DANGEROUS DRUGS.

THE Permanent Central Opium Board has been in session for the sixth time in pursuance of its duty to watch continously the course of international trade in dangerous drugs, and to ascertain whether excessive stocks have accumulated in any country in such a way as to suggest the possibility of illicit traffic. The recent arrival and disposal of 250,000 lb. of opium in China will doubtless engage the attention of the Board, the chairman of which declared "there is only one way to stop the illicit traffic, and that is to stop the surplus of drugs that is being produced throughout the world", a steamer shipped this contraband cargo at Bushire. By the provisions of The Hague International Opium Convention of 1912 statistical information as regards the trade in raw opium, prepared opium, morphine, cocaine, and their preparations was to be furnished in detail, as expeditiously as possible, by the contracting Powers. The Geneva Convention of 1925 which in the opinion of some strengthened and in the opinion of others in some respects weakened The Hague Convention, similarly required such information to be furnished to the Central Board and to the contracting Powers. Thirty-four Powers have now thus bound themselves to supply the statistical information required, under one or other of the foregoing conventions. Turkey and Persia, both large producing countries, have not hitherto deposited their ratifications, while China and the United States, it will be remembered, withdrew from the Geneva conferences which led up to the Convention of 1925. China, after ridding herself of opium before the civil war, has again become a large producing country; the efforts of the Nanking Government and the Young China Party are unable to overcome the action of the military provincial governors in fostering this profitable industry. The United States, which initiated the Shanghai Opium Commission of 1909 and the three Hague conferences of 1911-12, 1913, and 1914, and remains bound by the conventions drafted by those conferences, is no party to the Geneva Convention of 1925. The reason of that abstention was that by this latter treaty "the American principle for a limitation of production to medical and scientific purposes has not been included as a contractual obligation," as the chairman of the conference frankly admitted. It is nevertheless interesting to note, as pointed out by Mr. Alec Wilson in his *World Peace and American Policy*, that it was the deep interest which the United States took in the drug traffic that first led to direct contact between Washington and Geneva after America's refusal to join the League of Nations, a contact which has become closer year by year. The comparative non-success of the League in grappling with the enormous illicit traffic

in dangerous drugs serves to emphasize the necessity for a policy of limitation of production to medical and legitimate purposes, as advocated in these columns for many years, and approved by the Assembly of the League of Nations at its last meeting. How such limitation is to be secured by international co-operation, whether by a method of "rationing," or a "scheme of stipulated supplies" as approved by some Governments but not favoured by the Advisory Committee at Geneva, or on some other principle, will doubtless engage the consideration of the Permanent Central Control Board.

INTERNATIONAL CAMPAIGN AGAINST TRACHOMA.

AT the thirteenth International Congress of Ophthalmology, held at Amsterdam last year, it was resolved to found an International Anti-Trachoma Organization. This body has now been formed at Geneva, where the preliminary arrangements were recently concluded. The sessions, which took place in the Palace of the League of Nations, were attended by forty delegates representing twenty-one States. Professor Emil de Grósz, who presided, was elected president of the organization for five years, and Mr. A. F. MacCallan, C.B.E., F.R.C.S., of London was elected a vice-president. The secretary-general is Dr. Wibaut of Amsterdam. Other members will include representatives of the Hygiene Committee of the League of Nations, the Association Internationale contre la Cécité, and of the International Ophthalmological Council. Among the aims of the organization are: (1) to further co-operation for the prevention of trachoma, both nationally and internationally; (2) to support and propagate all measures directed against the disease; (3) to organize conferences with the object of elucidating the problems of its etiology, diagnosis, treatment, extension, and prevention, of discussing associated scientific and social questions, and of preparing necessary legislation. Reference was made to a special law that had been passed in Hungary as early as 1886 initiating a campaign against trachoma, and the opinion was expressed that such precautionary measures should be advocated in all countries exposed to risk. Japan was reported to have established a thousand centres for the treatment of half a million patients suffering from the disease. About a thousand specially trained doctors were stated to be engaged in this service, which had been estimated to cost the country half a million yen every year. At one of the sittings an address was delivered by Dr. Olitsky of New York on the significance of the bacillus discovered by Noguchi, and a demonstration was given by Mr. M. S. Mayou, F.R.C.S., of London. The League of Nations has issued a circular letter requesting its members to support the work of the organization. Professor Gourfein entertained the delegates to a luncheon at his Geneva clinic, and a dinner was arranged by M. André Patry, a Geneva oculist.

FOETAL GROWTH.

THE growth of the foetus, which forms the subject of an elaborate treatise recently published by Professors Scammon and Calkins,[1] may for merely descriptive purposes be studied by qualitative methods, the varying proportions exhibited by the component parts of the body during foetal development being ascertained by simple inspection. The obstetrician, however, requires a more accurate method, at least in connexion with the foetal head, and is forced to employ quantitative methods and exact measurements. The development of the body *in utero* also forms an important chapter in the biology of growth at a period when body changes are at their maximum; and, if the theory still holds that racial development is to some extent a reflex of embryonic development on a larger scale, the subject must be one of importance to the anthropologist. In this connexion a recent observation by Sir Arthur Keith, in reference to the relatively large cranial capacity of certain of the earliest prehistoric races and its reduction in later periods, is of interest. The opinion, he states, is gaining ground that the retention of infantile characters plays a part in the evolution of new human races. Scammon and Calkins's work deals with foetal growth from the third month, when all the organs have been laid down, onwards to the full term. It is based on thirty-five thousand determinations of seventy-one external dimensions of the body, the measurements being made on upwards of four hundred selected human foetuses. The analysis of the data collected is expressed in both graphical and numerical forms, and those who have unwisely neglected to familiarize themselves with mathematical reasoning may possibly not feel altogether at ease among the mathematical formulae. The conclusions of the research are, however, quite clear and comprehensible. The most important result of the work is the establishment of a new principle, that in general the linear growth of each individual part of the body takes place in uniform ratio during the foetal period, or, graphically expressed, that it is represented by a straight line. Presumably, each part has its particular and uniform rate of growth, so that the proportions of the various regions change during the foetal period, the lower limbs becoming relatively larger and the head relatively smaller. This newly recognized law is in complete harmony with the previously known "law of developmental direction" or "law of cephalocaudal development," defined by Jackson and Scammon as the tendency of development (including growth and differentiation) to start in the head region and progress towards the caudal region; and similarly, in the transverse plane, to progress latero-ventrally in the trunk and proximo-distally in the limbs. It is interesting to note that the general features of this law were adumbrated in Aristotle's *De Animalia*. Scammon and Calkins have included a complete tabulation of the extensive data collected by them, together with the determination of exact formulae for the foetal body length according to age, and for the different external dimensions in relation to body length.

MOSQUITOS IN BRITAIN.

IT is well known that the presence of mosquitos is not a serious menace to human health in these islands. We have, it is true, no fewer than three species of anopheles, none of them very rare, and each one known to be a carrier of malaria in other countries; but, owing probably to conditions of temperature, locally acquired infection is a rarity. Occasional deaths occur from septicaemia consequent on the bites of mosquitos, but these events also are exceedingly unusual. We may say, then, that the British mosquitos should be considered as a nuisance rather than as a menace to health, and this is fortunate, for we have some twenty-six species indigenous to our country. Some of those which breed in ponds cause inconvenience, as anyone may experience who visits the public woodlands round London at this time of the year; but by far the greatest nuisance is occasioned by two species which breed only in salt marshes round our coast. The same varieties of mosquito, or their near relatives, have attracted a great deal of attention in parts of Canada, New England, and elsewhere, and it may be stated generally that the salt marsh mosquitos are distinguished by inflicting an unusually painful bite, by their diurnal activity, and by their very great range of flight. They travel in from the Essex marshes and bite people in the London docks, so that it is

not surprising that in America, that continent of wide spaces and great distances, they are reputed to travel as much as forty miles. So far as Great Britain is concerned, the control of the mosquito which breeds in salt marshes has been worked out and applied by Mr J. F. Marshall of the British Mosquito Control Institute at Hayling Island. We understand that his home is on the island. But a few years ago it was customary for the residents to vacate their homes in July and August, and leave the island as far as possible to the mosquitos. Times have changed, the mosquitos have vanished, and the island is now populated at that season by holiday makers. In a pamphlet before us[1] Mr. Marshall discusses the organization of control. He shows that nothing effective can be done unless the particular species is identified; this is because different sorts of mosquito breed in different places, and it is idle to blame the domestic water butt if the insects are coming from a pond in a neighbouring wood. When the insect has been identified, its breeding-place may be located and abolished without great difficulty, for example, in the case of the salt marsh mosquito which breeds in brackish water that is not used by cattle, the mosquito larvae may be controlled by oiling the water or poisoning it with an appropriate dose of creosol. We commend the work of the British Mosquito Control Institute to medical officers of health, and others who are often asked for information which they are not always able to give. We can testify to the value of the advice which may be obtained there.

SUGAR DETERMINATION IN CONDENSED MILK.

A REPORT[2] by Dr. Monier-Williams, issued by the Ministry of Health, and entitled "The determination of sucrose, lactose, and invert sugar in sweetened condensed milk," will be of great interest to analysts, and to those concerned with questions of the standards of purity of manufactured foods. The booklet deals, primarily, with chemical methods. The problem of separating and estimating a mixture of carbohydrates is a difficult one: the measures taken by the author to surmount the difficulties are ingenious, and should prove helpful to other workers. Apart from purely technical matters, an interesting point which emerges is the significance of the presence of an appreciable amount of invert sugar in the milk. This, it appears, can be taken as an indication of dirty or inefficient conditions of manufacture, or of insanitary conditions at the source of milk supply. This fact should prove of the utmost value to those whose duty it is to see that proper precautions are observed alike by producers and manufacturers.

ROYAL MEDICAL BENEVOLENT FUND.

THE proceedings at the ninety-fourth annual meeting of the Royal Medical Benevolent Fund were reported in our issue of March 22nd (p. 561), and now the full record of the work done in 1929 has been issued to subscribers. Once again an earnest appeal is made to all members of the profession to support the Fund as generously as their means permit. Since 1835 nearly £300,000 has been expended by way of grants and annuities to medical practitioners or their families in distress. Grants are made only after careful inquiry, the amount depending on the needs of each case and on the total sum available at the moment. The income at the committee's disposal for the award of grants is derived wholly from subscriptions and donations, while annuities are paid out of the income from invested capital. More subscriptions mean more help to urgent cases of the kind with which our readers must be familiar from the pathetic notes supplied by the committee and published at intervals in these pages. Annuitants (numbering 119 last year) are chosen by the committee from the most necessitous of the grantees who have reached the age of 60: to extend this good work legacies are needed. The Guild, or Women's Branch, was formed twenty-one years ago to aid the Fund by obtaining further subscriptions and making the work better known, and by helping those beneficiaries of the Fund who are referred to it by the Case Committee. This help is given by means of grants for relief, maintenance, and education, gifts of clothing, home visits, and personal service. The education of children and their subsequent training to earn a livelihood are the Guild's special care. The address of the Fund is 11, Chandos Street, Cavendish Square, W.1, and of the Guild, Tavistock House North, Tavistock Square, W.C.1.

THE EDUCATIONAL NUMBER, 1930.

OUR next issue, dated September 6th, will be the annual Educational Number of the *British Medical Journal*. Its contents, as in previous years, will include a full account of the requirements of the General Medical Council and of the universities and other licensing bodies in Great Britain and Ireland, as well as information about the opportunities offered by the various medical schools and other teaching institutions, and the fees charged by each. The details given have been revised and brought up to date by the authorities concerned. These sections, the object of which is to furnish a handy guide to intending students of medicine, are supplemented by articles intended for newly qualified practitioners on such matters as post-graduation study in Great Britain, the public health services, tropical medicine, psychological medicine, and the various special diplomas. In the sections dealing with the public services will be found a concise account of the *present terms and conditions of service in the R.N.M.S.*, the R.A.M.C., the I.M.S., and the R.A.F.M.S., which the Representative Body of the British Medical Association has decided are satisfactory and such as can be commended to the notice of the younger members of our profession. The opening article for this year's Educational Number, entitled "A Review of the Medical Curriculum," has been written by Dr. H. R. Dean, professor of pathology in the University of Cambridge.

We learn that the reception room in the Winnipeg Winter Club, where members registered on arrival, has been a busy centre from Monday morning onwards. Early on Tuesday the President-Elect opened the scientific and commercial exhibitions, both of which are housed there. Next came the Adjourned Annual General Meeting of the British Medical Association, preliminary business having been disposed of in London on July 22nd. After the ceremonial induction of Professor Harvey Smith as President for 1930-31 at the hands of Professor Arthur Burgess, the Premier and the Mayor made speeches of welcome, and delegates from this country and elsewhere were formally introduced to the President. Professor Harvey Smith then delivered his Presidential Address, of which the text appears in the opening pages of our special *Canadian Supplement*. At 3 o'clock the members assembled again and walked in procession to the Cenotaph, after which a religious service was held in the grounds of the Parliament Buildings. Tea in the Winter Club, a lacrosse match, and private dinner parties were followed by the President's reception, and dancing and music, in the Parliament Buildings. The opening meetings of the Scientific Sections on Wednesday, August 27th, were well attended, and much interest was shown in the discussions arranged. Up to Tuesday night the number of registrations was 2,900.

MEDICAL CONDITION OF THE CASUAL POOR.

Report of the Departmental Committee.

In September, 1929, the Minister of Health appointed a departmental committee to consider the problems concerned in the relief of the casual poor, under the chairmanship of the Rev. L. R. Phelps, and this committee has now issued its report. Its terms of reference were "to inquire into the administration of the laws relating to the relief of the casual poor, and to make recommendations with special regard to the assistance of persons seeking work, and to persons suffering from physical or mental disability." Of the hundred pages of the publication fifty-one are devoted to the report and the recommendations, the remainder being utilized for appendices, the first fifteen pages of which are occupied by the reprinted history of vagrancy, contained in the report of the Committee on Vagrancy of 1904-6. Nearly thirty pages, however, are filled with the report of a special investigation made for the departmental committee by Dr. E. O. Lewis, inspector of the Board of Control.

It should be noted that the publication under review is limited to the consideration of the "casual poor" only, a casual poor person being defined by the Poor Law Act of 1930 as any destitute wayfarer or wanderer applying for or receiving (poor) relief. It does not include, consequently, the homeless poor who do not apply for relief. Of these "casuals" there have scarcely ever been less than nine thousand accommodated nightly during the past three years, and the average number may be put at twelve thousand. Dr. Lewis made a careful, though necessarily not an exhaustive examination, of a 5 per cent. sample of this population, the actual numbers being 542 men and 50 women, drawn from about an equal number of casual wards in industrial centres and in agricultural areas. The primary object of the inquiry was the investigation of abnormal mental conditions among those examined, though a considerable amount of information was gathered in regard to the physical and social conditions of those coming under observation.

Mental Deficiency.

Of the 592 casuals examined 93 were mental defectives (about 15.7 per cent.); if this percentage is applied to the total casual population of 12,000, it is estimated that there are nightly about 1,800 mental defectives in casual wards in England and Wales. These persons were all feeble-minded (none of them imbeciles or idiots), with an average mental age of 8 or 9. They were for the most part sub-normal in physique and poorly clad as compared with the ordinary casual, their clothing being torn and dirty, and their feet frequently showing sores from the lack of necessary attention. Taking those of higher mental grade than these defectives, the majority were still found to belong to the dull section of the community, although there were several of normal intelligence, and some even above the average, but these formed a small minority.

Of the whole group examined 32, or 5.4 per cent., were insane; of these 20 were suffering from senile dementia, 2 from dementia praecox, 4 were manic-depressives, 3 had a toxic psychosis, and 3 were paranoiacs. In addition to the mentally deficient and the psychotic, there were 34 (5.7 per cent. of the whole) who were psychoneurotic. The anxiety neurosis was the commonest form, but there were several cases of the psychasthenic type, and a few (for the most part women) hysteric, though the coincidence of chronic alcoholism in practically every one of these made it difficult to say whether the hysteria was dependent on an original mental instability or was mainly alcoholic. A diagnosis of chronic alcoholism was made in 75 cases altogether, including those just mentioned.

Other Morbid Conditions.

Affections of the circulatory system were found in 43 cases. Comparatively few respiratory and digestive diseases were detected, bronchitis being the most common, but 5 persons had symptoms of gastric or duodenal ulcer. Defects of vision were not uncommon, and the disability was, as a rule, imperfectly corrected by the glasses worn or possessed. There were 17 cases of hernia, 6 of hydrocele, and 2 of varicocele, the last two conditions being for the most part extensive owing to neglect of operations which had been proffered. The small number of cases of osteo-arthritis and of skin conditions was surprising.

Medical Recommendations.

The chief practical conclusion arrived at by Dr. Lewis, especially on a review of the mental conditions found, is that there is need for the periodical medical examination of all casuals. He emphasizes the point that medical practitioners who undertake these examinations should have a special knowledge of psychiatry and kindred studies, and be keenly interested in this branch of medicine. It is stated that the Mental Deficiency Committee estimates the incidence of mental defect in England and Wales to be about 8 per thousand of the population, whereas similar tests indicate about 15 per cent. in this group of casuals.

Dr. Lewis adds that in his experience the casuals he examined compared favourably with those men and women found frequently in the common lodging-houses of some provincial towns where there is lax supervision; he pleads for closer co-operation in the administration of casual wards and common lodging-houses.

Summary of General Recommendations.

In its general recommendations the committee envisages the continuing of the casual ward system for some years, though it looks forward to the time when the stopping of vagrancy at its sources may render them unnecessary. It recognizes that the taking over of the functions of the guardians by the county and county borough councils will make the task of dealing with the casual easier, but recommends that a further process of co-operation of authorities should be encouraged by the splitting up of the country into some dozen areas, under *ad hoc* vagrancy committees, with a special visitation officer in each area, a hostel and training centre for the reception of casuals desiring to come off the road, a medical staff, and an advisory committee linking up the various voluntary agencies with the local representatives of the Ministries of Health and Labour, the watch committee or standing joint committee, and the public assistance authorities.

Casual wards should be distributed along the main lines of vagrant traffic at intervals of about fifteen miles, and be separate from any other institution. They should be staffed with trained officers whose whole time would be devoted to the relief of casuals; in certain cases they might be assisted by part-time officers. Detention should continue for two nights, except in the case of those who carry "vacant tickets" and are being passed on quickly by employment exchanges in search of work. Every effort should be made to keep off the roads men who are fit and ready for work; their care should be the concern of the Ministry of Labour, and not of the vagrancy committees. Proper arrangements should be made for bathing, sleeping, cleansing, feeding, and work, along the lines already laid down by order, and maintained by the better authorities. It is reported, however, that "in a certain number of casual wards the conditions now existing are infamous and intolerable."

The committee adds: "With certain safeguards against the admission to casual wards of persons who could if they liked provide for themselves, a general raising of the standard of accommodation and treatment would not tend to attract men to a life of vagrancy, but would have the result of improving the self-respect of the casual population and making it easier for them to regain their proper places in the life and work of the community." Detention colonies should not be looked upon as the special province of vagrancy committees, but they should provide for the whole of the class which "needs something by way of compulsion to rehabilitate it."

Provision should be made for more systematic medical inspection; and while parliamentary powers would be required for the introduction of any complete system of registration of casuals, some steps might be taken to prepare a central register of those who frequent casual wards, with reference to their age (under 5, 14, and 25), to their degree of physical or mental fitness, and to the amount of assistance previously received from training courses.

Women casuals should be relieved in the main part of the Poor Law institution, and not in the casual ward; the work of women inspectors should be extended. A tribute is paid to the good work of the Salvation Army, the Church Army, the *Morning Post* Embankment Home, and similar agencies; it is suggested that their methods should be studied, and the best features be adapted to public institutions. The comment is made: "We should welcome the provision of similar homes in other parts of the country."

Co-operation between vagrancy committees, employment exchanges, and voluntary bodies, however important and even necessary they may be, will not result in satisfactory progress unless with full co-operation of the general public, who should be made to feel that the provision for the casual wayfarer was such as to render begging for food and shelter unnecessary and unjustifiable.

A STANDARD FOR THE ANTIRACHITIC VITAMIN D.

STATEMENT BY THE MEDICAL RESEARCH COUNCIL.

THE following statement has been sent to us by the Medical Research Council for publication.

The Medical Research Council's Committee on Accessory Food Factors has long attempted to find generally acceptable conventions for the quantitative record of the activities characteristic of the different accessory factors, or so-called "vitamins." As in other instances, any unit of activity based on the production of a stated degree of a biological effect, however carefully this may be defined, must be liable to wide variation with differences in the conditions under which the test is conducted. This is especially so in testing for a vitamin action, where the effect on which measurement is based is the correction of an abnormal condition produced by a deficient diet. The severity of the condition to be treated will vary with differences in the dieting and treatment of the experimental animals, as well as with racial and individual differences in the stocks. Other biological standards, such as those for serums and hormones, held by the Council's Department of Biological Standards, are based on stable standard materials, in terms of each of which a unit of activity is defined which is independent of the details of the biological method used in its measurement. Here a measurement of activity in units is made on a strictly comparative basis, with reference to the standard.

With regard to the antirachitic vitamin known as vitamin D, this necessity for a common material standard was recently emphasized in the following recommendation by the committee:

"Any unit or standard based directly on the response of the experimental young rats to administration of antirachitic material is unsatisfactory, owing to the disproportionate variation in the response to equal doses of apparently similar animals, when tested at different seasons of the year or bred in different laboratories. The vitamin D unit should rather be referred to a stated quantity of some standard antirachitic material, with which comparison can be made by any reliable biological method."

Standard Adopted by Pharmaceutical Society.

The discovery of the method of producing this vitamin artificially from ergosterol has led to its manufacture on a large scale, its issue in many forms for therapeutic use, and its addition to various types of food materials. The proper desire of manufacturers to use and to supply such preparations with a quantitative indication of activity has led to the appearance of several unofficial "units," mostly defined in terms of some biological effect, and having no clearly determined relation to one another. The need for a common basis of measurement is therefore accentuated, in this case, by an existing and growing confusion. One of the provisional units current in this country —namely, that adopted by the Pharmaceutical Society's Laboratories when reporting on the vitamin D content of materials submitted to them for assay—has, indeed, been based on a material standard consisting of an oily solution of irradiated ergosterol, supplied to them for this purpose by the National Institute for Medical Research. Only a small quantity of this material had been prepared, however, and sufficient data were not available to justify the assumption that it would have the stability necessary for a standard and allow the committee to recommend it for general use.

Establishment of a New Standard.

It was accordingly decided to arrange for the preparation by the National Institute of a similar solution, on a scale sufficient for its eventual distribution to the numerous laboratories or institutions likely to require it, and to organize an investigation of its properties by different experts working on behalf of the committee. A quantity of ergosterol from yeast, purified and dried by methods carefully recorded, was subjected, in an accurately made alcoholic solution, to irradiation with the rays from a mercury arc, the physical details of the procedure being measured and recorded with the greatest practicable accuracy. All conditions known to influence the amount of vitamin D formed should therefore be reproducible at any future date, or in any other laboratory, leaving only the final adjustment of a new standard to equivalence with this original one to be made on the basis of comparative biological assay. The irradiation products were carefully freed from alcohol, dissolved in pure, unadulterated olive oil, and the volume adjusted to produce a known concentration, in terms of ergosterol used. The solution was then placed, and its main bulk has since been kept, in the Institute's refrigerating chamber, at a temperature of −4° to 0° C.

Evidence of the stability of such a preparation, under different conditions and over a sufficiently long period, being of central importance for a decision as to its use as a standard, the investigations promoted by the committee have, of necessity, been of a corresponding length. The experimental results from the different contributing laboratories have recently been completed, and have now been carefully reviewed by the committee, which has stated its conclusion from them in the following terms:

"From these tests it appears that specimens of irradiated ergosterol, prepared in the manner described above, do retain their activity unchanged for two years if maintained at or below 0° C. If they are kept at room temperature loss of activity may occur."

Definition of Unit Activity.

The evidence of the different investigators being uniformly favourable as to the suitability of this solution in other respects for use as a standard in comparative biological measurement of vitamin D, the committee decided to recommend its adoption as a standard, and the definition of a unit in terms of it, and adopted the following resolutions:

(*a*) That the standard solution of irradiated ergosterol prepared and maintained by the National Institute for Medical Research be recommended for adoption as a standard for the comparative estimation of vitamin D.

(*b*) That the unit of vitamin D be defined as the antirachitic potency of a quantity of this preparation corresponding to 0.0001 *mg.* of the ergosterol used in its production.

(*c*) That either the *x*-ray method, the "line test," or chemical analysis of the bones of the experimental animals, be recommended for use in the estimation of vitamin D.

(*d*) That supplies of the standard material be made available for general distribution from the National Institute for Medical Research, Hampstead. As the supply is limited it is hoped that users will themselves prepare standard solutions of irradiated ergosterol for use in individual tests, retaining the National Institute's material for reference. It is important that all such standard materials be kept at temperatures not exceeding 0° C.

It may be mentioned that the unit recommended has the same value, in terms of the weight of the original ergosterol represented, as that used for some years past in the Pharmaceutical Society's laboratories, on the basis of the provisional standard solution supplied to them. The standard solution now recommended for general use cannot be assumed to be exactly equivalent to this, though comparative tests have not revealed a measurable difference. Apart from such difference as may exist, the unit now proposed will, therefore, correspond to one of those already current.

It is of convenient size, as representing the order of dose required for daily administration to a rat, to produce healing of rickets in a curative test; that is to say, the daily dose suitable for the conditions of a particular test will be neither a large multiple nor a small fraction of the unit proposed.

The committee mentions three biological methods of estimating antirachitic effect which it is able to recommend, although its recommendations on this matter are obviously not meant to be exclusive. It has mentioned the methods in which, from experience of its own investigations, it has confidence; but its statement is not intended to preclude the use of other biological methods that already exist, or of better ones that further investigation may produce, provided that in every case the test is based on a comparison with the fixed standard.

Distribution of Standard Solution.

As indicated in another of the committee's recommendations, the quantity of the standard solution available will not allow it to be circulated in large quantities. Its distribution will, of necessity, be limited to those institutions which have the staff and equipment needed for its accurate application in biological assay, including proper facilities for its preservation without loss of activity. Unless the number of institutions requiring it prove to be much greater than that to which other standards are distributed, it should be possible to supply samples once or twice a year to each regular recipient for some years to come, before the preparation of a new batch of the standard solution will be required. It is proposed to make the first issue about the end of September, and a memorandum giving details for the use of the standard will be sent with each first sample. It will greatly facilitate the completion of arrangements if applications from institutions wishing to receive the standard are made as early as possible, so that the department may be able to estimate the number of separate samples likely to be required for the first and subsequent issues. All such applications should be made to the director of the Department of Biological Standards, National Institute for Medical Research, Hampstead, London, N.W.3.

Ireland.

Obstetrics and Gynaecology in Dublin.

THE August issue of the *Irish Journal of Medical Science* is of particular interest to obstetricians and gynaecologists, as has been the case with the corresponding numbers of this periodical in previous years, being largely devoted to the publication of the reports of three Dublin hospitals—namely, the Rotunda Hospital, the Coombe Hospital, and the National Maternity Hospital. Reference was made last week (p. 298) to the valuable report issued by the Master of the Coombe Hospital of the work carried on there during 1929. In his account of the progress of the Rotunda Hospital, the Master, Dr. Bethel Solomons, expresses the hope that the new wing will be completed early next year; there will then be available an additional operating theatre, the long needed increase of accommodation for the nursing staff, and a new story for the pathological laboratory. During the twelve months from November 1st, 1928, to October 31st, 1929, 2,382 women were admitted to the wards of this institution, of whom 2,034 were delivered; 1,805 women were delivered in their own homes. Certain tabular changes have been made in the present report as compared with those of previous years. Thus, a smaller statistical table relating to disproportion is substituted for the more extensive one hitherto compiled, and the Caesarean section table has been rearranged to distinguish three procedures—namely, the classical, the lower segment, and repeat operations. Only one case of ophthalmia neonatorum occurred during the year, and tribute is paid to the efficiency of the 1 per cent. solution of silver nitrate, which is applied as a routine prophylactic. Among fifty-seven oil and quinine inductions of labour there were two infantile deaths; these did not appear to be attributable to this procedure, which is regarded as being very safe. Difficulty is still experienced in persuading patients to attend the ante-natal clinic; it is suggested that in order to diminish maternal mortality it may be necessary to withhold maternity benefit in such cases, or to take some other similarly drastic step. The fact is emphasized that in the great majority of the cases dealt with in the Rotunda Hospital during the year there had been no ante-natal care. Disproportion cases numbered 108; they ended spontaneously in thirty-four instances, in version and delivery in seven, and in Caesarean section in thirty-five, while forceps were required on forty-seven occasions, and destructive operations on five. There were thirty-seven cases of marked inertia; this was nearly always treated on academic lines. Dr. Bethel Solomons continues to classify this condition as early and late, primary and secondary, believing that in this way simplicity in treatment is facilitated. In one case of inertia most satisfactory results followed the intrathecal injection of 1 c.cm. of stovaine. In the whole series of cases, forceps were applied on 138 occasions, an incidence of 6.7 per cent. The gynaecological side of the hospital was again very active, although it was necessary to close one of the large wards during the building of the new wing, extra beds being placed in the other wards. In spite of this diminution of the accommodation the number of admissions (748) was larger than ever, and the record for the hospital was again beaten; of this number 654 were operation cases. The Master of the National Maternity Hospital, Dr. Patrick T. McArdle, reports that during the twelve months April 1st, 1929, to March 31st, 1930, 961 patients were delivered in the wards and 614 in the maternity service. In the gynaecological department 371 operations were performed. There were 7,843 attendances at the dispensary, including ante- and post-natal maternity patients, and infants under one year of age; there was an increase of 1,657 patients over the total of the previous year. The morbidity rate in 961 intern patients (calculated by the standard of rise of temperature to 100° F. on any two occasions) was 3.01 per cent. The death rate in the hospital for acute septicaemia was 0.104 per cent. The number of cases of acute eclampsia seems to be diminishing, but the admission of cases of eclampsism is increasing, this being due to the larger number of patients now attending the ante-natal dispensary. Eclamptic patients are treated on conservative lines, the only operative procedure being delivery by forceps as soon as the os is dilated. The convulsions are controlled by the free use of morphine and chloroform, the colonic lavage being repeated if the fits recur. During the year fifty-nine patients were delivered by forceps, representing 6.1 per cent. of the total deliveries. It is still considered necessary to employ the Kielland forceps in cases of high transverse arrest of the vertex in flattened pelves, also in rotating persistent occipito-posterior, mento-posterior, and low transverse arrest of the vertex. This issue of the *Irish Journal of Medical Science* contains also a thoughtful account by Dr. F. W. Doyle of the employment of gas and oxygen anaesthesia in obstetrics. It is held that the results so far obtained are sufficiently encouraging to stimulate an interest in what appears to be an ideal anaesthetic and analgesic, from the point of view of the requirements of obstetrical work. Dr. Bethel Solomons reports a case of adenocarcinoma of the cervix in a nulliparous woman. Dr. R. E. Tottenham contributes a short account of obstetrical and gynaecological clinics in Vienna, Paris, Sweden, and Denmark.

Improvement of County Homes.

At the Public Health Conference in Dublin, Mr. A. P. Delany, local government inspector, read a paper on the improvement of the county home. He said that although certain enactments had been passed by the Irish Parliament before the Act of Union, the Poor Relief (Ireland) Act, 1838, which was modelled in all essentials on the English Poor Law Amendment Act, 1834, was the measure with which until quite recent years they had been familiar in Ireland. The number of unions formed at first was 130; these were increased in 1848 to 131, and in 1850 to 163. Between 1850 and the outbreak of the European

war in 1914 five unions were dissolved, and the areas which they served were added to adjoining unions. Of the remaining 158 separate unions, 131 were in the present area of the Saorstát. With the establishment of the Free State the workhouse disappeared, at any rate in name; it was now the county home. Mr. Delany feared that the change of name was the principal change that had occurred, and that the characteristics were largely unaltered. It could hardly be necessary to say that a county home should not continue the bad aspects of the workhouse, which it replaced; it should not be a compound where the poor were herded like cattle, or have the primitive horrors of a prison. If the county home had any of these features the schemes introduced nine or ten years ago had failed and, however unpleasant it might be to admit it, they were still administering the workhouse system.

The Down County Mental Hospital.

The Down County Mental Hospital, Downpatrick, was founded in 1869, and has since then undergone a considerable amount of structural alteration and extension; at present it has accommodation for 420 men and 420 women. In his annual statistical report for the year ending December 31st, 1929, Dr. M. J. Nolan, the resident medical superintendent, mentions that at the close of the year under review there were in residence 400 men and 374 women. He remarks that this margin of vacancies, besides being of great advantage from an administrative standpoint, is of very considerable monetary value to the county, since it enables the committee to undertake the treatment of paying patients from outside the district. During 1929 there were admitted 69 men and 62 women, this figure exceeding by 34 the number admitted in 1928. Of 55 patients who were discharged, 47 had recovered, 7 had been relieved, and 2 were unimproved. The death rate during the year was considerably increased by a wave of high mortality which swept over the country, resulting in the deaths of many senile patients and of younger patients, following influenza. Dr. Nolan points out that the probable improvement in the administration of lunacy laws which future years will bring must necessarily entail some degree of increased expenditure on the Down County Mental Hospital. It is hoped that during the present year a fully equipped building for electro-medical and hydrotherapeutic treatment will be brought into being, and additional verandahs and shelters provided. The scope of treatment is being widened by the extension of occupation therapy, and special rooms are provided for such activities as basket-making, raffia, leather, and wool work.

Scotland.

Department of Health.

DR. J. L. BROWNLIE, M.D., D.P.H., who is at present county bacteriologist and pathologist in Lanarkshire, has been appointed a medical officer of the Department of Health for Scotland. Dr. Brownlie graduated in medicine at Glasgow University in 1913, took the diploma of public health (Cambridge) in 1916, and proceeded M.D., with high commendation, in 1918. Among his previous appointments are those of resident medical officer for several years in Glasgow fever hospitals, and that of assistant bacteriologist for six years in the Glasgow Corporation Laboratory. He has completed some promising research work, and made a number of contributions to medical literature.

Presentation to Dr. P. Murray Kerr.

Dr. P. Murray Kerr, T.D., J.P., who recently retired from the post of senior surgeon to the Dumfries and Galloway Royal Infirmary, was the recipient of a public testimonial at a large gathering on August 20th. A native of Dumfries and graduate of Edinburgh University, Dr. Kerr succeeded his father in practice in 1890, and has been associated with the infirmary for thirty-six years. For a time he was president of the Border Counties Branch of the British Medical Association. In addition to his many medical activities, he has been closely identified with numerous aspects of public life in the town and district. A keen Volunteer and Territorial, he succeeded to the command of the 5th King's Own Scottish Borderers in 1911. In 1915 he went out to the Dardanelles as its commanding officer, but contracted dysentery and had to be invalided home. In 1920 he was made honorary colonel of the battalion. In the early part of this year he was appointed honorary sheriff-substitute of Dumfriesshire. Provost Brodie made the presentation of an illuminated address, a radio-gramophone, and a cheque to Dr. Kerr, and referred appreciatively to his services as surgeon, citizen, and soldier. With him was associated Mrs. Kerr, to whom a tribute was paid by Sir James Crichton-Browne. Many letters of apology for absence were read, including one from Dr. Joseph Hunter, M.P., a former colleague.

Scottish Vital Statistics.

The main features of the vital statistics of Scotland for the second quarter of the year are a birth rate of 20·4 per 1,000, a marriage rate of 6·8, a death rate of 13·1, and an infantile mortality rate of 73 per 1,000 registered births. The birth rate is 0·9 below the mean of the rates for the second quarters of the preceding five years, and 5·5 below the mean of those for the second quarters of the preceding ten years. The death rate, 13·1 per 1,000, is 2·7 less than in the previous quarter, and slightly below the mean for the second quarter of recent years. The infantile mortality rate of 73 per 1,000 is the lowest recorded for any second quarter since 1913, the earliest year for which quarterly infantile mortality rates for Scotland are available.

England and Wales.

The New Housing Act.

THE Ministry of Health has issued a circular (No. 1133) to county councils, county borough councils, and other local authorities in England and Wales which are concerned, directing their attention to and setting out the provisions of the Housing Act 1930 which came into operation on August 16th. In an introductory note the Minister reminds authorities of the principal objects of the Act which are to facilitate the task of clearing away existing slums and to prevent the deterioration of other areas and the consequent creation of new slums. To meet the economic difficulty of rehousing slum dwellers at rents which they can afford to pay, increased financial assistance on a new basis has been provided, this will be available to local authorities for rehousing not only persons displaced from clearance and improvement areas, but also those who have to leave individual houses about to be demolished. The Minister urges on local authorities the need for working to a definite system, which will co-ordinate the work of clearance and rehousing under the new Act with the ordinary building of new houses with assistance under the Housing (Financial Provisions) Act, 1924. Under the new Act it is the duty of every local authority to consider the housing needs of its area, and, as often as occasion arises or within three months of receiving notice from the Minister, to submit proposals for the provision of new houses. Furthermore, the authority of every area having a population of over 20,000 should submit in the present year a programme of the steps it proposes to take during the ensuing five years for dealing with the housing problem of its area. The Minister takes the view that local authorities will avail themselves of the financial assistance under the Act of 1924 to meet their ordinary housing needs, depending on the assistance provided by the new Act to meet the expense of moving dwellers in unhealthy areas to better homes. He draws the special attention of councils and rural district councils to the provisions contained in Part IV of the Act regarding housing in rural districts, pointing out that the proper housing of agricultural workers forms a vital element in any progressive agricultural policy, and appeals to the responsible local authorities to formulate plans without delay for dealing comprehensively with the housing needs of rural areas. Copies of the circular may be obtained from His Majesty's Stationery Office (price 6d.).

Malaria Therapy in the Cardiff Mental Hospital.

At the City of Cardiff Mental Hospital, according to the annual report for 1929, the serum of every newly admitted patient is tested for the Wassermann and Sachs Georgi reactions, in order to ensure that no early case of general paresis shall be missed. Dr. P. K. McCowan, the medical superintendent, is of opinion that the early diagnosis of general paresis has become more than ever an urgent practical problem, since it has been established that a considerable proportion of sufferers from this condition can be highly benefited by malaria therapy. At the institution under his supervision the routine serum examination is followed by a complete examination of the cerebro-spinal fluid of every patient with a positive reaction or in whom there are any clinical signs whatever suggestive of syphilitic involvement of the central nervous system. Cases diagnosed as general paresis are treated by a combination of induced malaria and the administration of tryparsamide, preferably in this order; but to patients whose physical condition contraindicates the induction of malaria the arsenical treatment is given first. In the ordinary way tryparsamide is given two months after the subsidence of the malaria, the interval being allowed on the grounds that it seems inadvisable to give an antimalarial drug when it is known that the good results of malaria therapy continue to show themselves for some months after the malaria has stopped. The preliminary dose of tryparsamide is 1.5 grams, and this is followed by seven weekly doses of 4.5 grams. The results have been very satisfactory, especially in early cases.

Mental Diseases Research in Birmingham.

In his report for the year ended March 14th, 1930, Dr. F. A. Pickworth, director of the laboratories of the Joint Board of Research for Mental Diseases of the City and University of Birmingham, records further progress in the investigations he and his co-workers have been conducting on the primary changes that occur in chronic mental disease, especially those in the neighbourhood of the brain. Post-mortem examinations have substantiated their previous findings, to which reference has been made (*Journal*, July 27th, 1929, p. 162), that macroscopical changes in the sphenoidal sinuses and the antra are present in persons with chronic mental disorder. In some cases they have found adhesions in the region of the middle fossa, between the pia-arachnoid and dura mater; from this they deduce that previous mild sepsis has extended by way of the fifth nerve to the brain membranes. In many post-mortem examinations, even on elderly patients, they have detected distinct adenoid remnants, with a pustular condition of the tissues in the neighbourhood of Rathke's pouch. The investigation of the spread of actual organisms to the brain membranes is being continued, and to this end a number of experiments with animals are in progress. In the bacteriological laboratory it has been found, as in previous years, that a large proportion of newly admitted patients give a positive agglutination reaction to the paratyphoid and dysentery groups of organisms.

Correspondence.

MASSIVE COLLAPSE OF THE LUNG.

SIR,—Dr. Woodburn Morison's ingenious explanations of the pathogenesis of massive collapse of the lung, which were published in the *Journal* of August 16th (p. 237), add peculiar interest to his recent British Medical Association Lecture on this clinical condition, and help us to understand many of the difficult problems this subject presents.

In his summary Dr. Morison maintains that "the weight of evidence is in favour of the theory that spasm of the bronchial musculature is the essential feature of active lobar collapse, but the disturbance of the sympathetic innervation must also be taken into account." He recognizes two stages in acute lobar collapse, the first being a dilatation of the bronchi of the area of lung involved, due to reflex irritation of the sympathetic, and leading to accumulation of mucus in the bronchi; from this stage early recovery is not infrequent.

This active dilatation, so he suggests, is usually succeeded by bronchiolar spasm, which causes the lobar collapse, and in support of his contention he states that in cases of asthma it is evident that spasm does occur in the lung. Now this is rather begging the question, for it is not evident that spasm does occur in cases of asthma; if it does it is quite exceptional. But why introduce the idea of "spasm," which is merely an ingenious hypothesis in cases of massive collapse? Is not the pathogenesis of acute lobar collapse more simply and completely explained by a paresis or paralysis of the physiological rhythmical dilatation and contraction of the bronchi in inspiration and expiration, which I described in 1903 in the March number of the *Bristol Medico-Chirurgical Journal*? At birth the solid lung is expanded and the alveoli are filled with air by this physiological mechanism, and if for any reason the mechanism fails in any area the corresponding lung remains in a condition of atelectasis. In later life bronchioles, previously dilated and now actively dilating and contracting, may become paralysed when the regions of the lung they supply revert approximately to the pre-natal state of collapse. When such paralysis is a temporary inactivity and passes off, the rhythmical contraction and dilatation is resumed, and the collapsed lung becomes re-inflated, just as it did originally at birth.

The ball-valve theory of Gairdner to account for lobular collapse of the lung is rightly set aside by Morison as untenable; the mucus that often collects and fills the lumen of a paretic bronchus is a passive collection, quickly expelled as soon as the bronchus resumes its normal physiological contractions and dilatations. Furthermore, it seems more probable that sudden spasm of the bronchi and bronchioles must lock up the air in the corresponding pulmonary alveoli, and then no collapse could occur until such contained air was absorbed, a process by no means sudden.—I am, etc.,

Bristol, Aug. 25th. PATRICK WATSON-WILLIAMS.

OBSERVATION AND EXPERIMENT.

SIR,—In the *Journal* of August 16th (p. 266) Dr. Manson expresses the hope that medicine will pass beyond the practical aim of curing illness and seek to become a true science giving "its own unique contribution to abstract thought and philosophy." In order to do this, he rightly says that the phenomena of the "sick man" must be studied. That means that medicine must concern itself with the individual rather than with the disease. As soon as it does so the student will find that he is confronted with problems, not only of anatomy and physiology, but also of psychology; the result of this triune study may well prove a revolution in medical thought and practice. It is not so long since it was considered a daring innovation to suggest that functional complaints such as the various neuroses might have purely functional causes, while to hint that organic disease might be influenced by emotional stress was rank quackery.

To the interested onlooker, however, it is apparent that a leaven is working in the profession which is considerably modifying the dogmatic materialism of the past. Within the last year the medical officer of health of a large industrial centre has published a book in which he refers to both cancer and phthisis as being primarily neuroses, and, moreover, suggests that wrong thinking may prove to be the determining factor which changes a harmless microbe into a virulent one. He thus makes a very definite approach towards the standpoint of Christian Science, which, after all, must have some sort of foundation on which to support its vast edifice. About the same time a well-known dental surgeon published a paper in which he asserted that mental worry was the cause of pyorrhoea—thus removing the quadruped from the rear of the vehicle and putting it for the first time in its proper place. Still more recently an eminent surgeon has committed himself to the statement that most of us suffer off and on from ulcer of the stomach or duodenum, and that worry and overwork may cause the symptoms to become acute.

A much more notable advance is made by Dr. Hazlett Frazer, whose letter was also published in the *Journal* of August 16th. He courageously claims for nervous strain a very important part in the etiology of rheumatic affections, and even advocates treatment by psychological analysis. Startling though this suggestion may seem to some, to future generations it will perhaps appear more remarkable that for centuries the medical profession should have been aware of the fact that a fit of temper frequently results in an attack of gout, and yet fail to make the deduction that mental states may be the deciding factor in other metabolic changes. There has been some recognition of the fact that worry predisposes to diabetes, but hitherto these things have been treated as isolated facts, and not built, as they should be, into the integral structure of medicine. Even though every woman knows that nerve strain, or even actual willing, can delay the incidence of the menses, it was possible for a distinguished gynaecologist the other day to mention a thorough knowledge of anatomy and physiology as the essential equipment for his specialty, and omit all reference to the woman's psychology. Still, as I have said, the leaven is working, and when at length a true science of medicine is in existence it may well be that psychology will play the part of the corner stone which was once rejected.—I am, etc.,

Birmingham, Aug 23rd. R. MACDONALD LADELL.

CHLOROFORM IN LABOUR.

SIR,—I had hoped to see some comment on the article on the action on the human uterus of anaesthetics, by Drs. A. W. Bourne and J. H. Burn, in the *Journal* of July 19th (p. 87). The aim of the writers was good, for investigation into that subject is overdue; but their results appear to invite discussion. In the absence of more authoritative criticism, may I raise a few points on their observations regarding chloroform?

After an introduction concerning the apparatus used they proceed, "We now describe records showing the effect of . . . chloroform"; later they say, "It seems elementary that for any final decision . . . there should be a clear mental picture of what this action is"; then they furnish two records—one lasting for twelve minutes of anaesthesia (how deep they do not state) in the first stage of labour; the other taken during a fifteen minutes' administration in a "fully developed second stage," where the depth, they admit, never attained "full surgical anaesthesia." A single confinement might have yielded both records, or the data may have been drawn from two confinements; but obviously the scope of the investigation was very restricted, and the authors do not state whether the patient was a primipara, young or old, weak or strong, or nervous or indifferent. "But," they conclude, "from the point of view of the patient there seems little doubt that the use of chloroform is not in keeping with modern enlightenment." I submit that they have not shown the effect of chloroform (but only a part of its effect in one or two individuals), that their conclusions are premature, and that we still lack that "clear mental picture" without which it is idle to credit ourselves with "modern enlightenment."

My points (based on the clinical experience of over thirty years in general practice) are as follows.

1. Idiosyncrasy plays a big role in chloroform anaesthesia: in one person a few drops may secure profound unconsciousness, while an ounce fails to achieve it in another. To generalize from one or two experiences, therefore, is never safe, and to dogmatize is unwarranted.

2. In some cases, notably in those susceptible individuals who swiftly attain deep anaesthesia under very little chloroform, uterine contractions continue almost unabated throughout; usually, however, the first effect of the administration is to diminish or stop the pains for a period of ten, fifteen, or twenty minutes, after which labour in most cases appears to go on with at least the same energy as (and sometimes more than) previously. I do not possess "a simple apparatus for recording graphically the changes in the intrauterine pressure"; but I have attended hundreds of women in deep anaesthesia who have delivered themselves unaided by forceps.

3. I am glad to note the evidence of the authors that "in a series of 562 cases [with chloroform] there has been no increase in the incidence of post-partum haemorrhage." That is a fact to drive home. My experience goes further. Thirty years ago, when the use of chloroform was occasional and tentative, post-partum haemorrhage was a very real risk, arising fairly often, now it is non-existent, or seems so. In twenty years, with practically every patient deeply anaesthetized, I have never had a serious instance of haemorrhage. The common cause of post-partum haemorrhage is exhaustion.

4. An obstetrician accustomed to secure full surgical anaesthesia from the moment his patient is having pains every five minutes, with a thinned os dilated to an inch and a half in diameter, will seldom quarrel with chloroform. I assume that he keeps a watchful eye and ear upon his patient. A woman in labour is for such anaesthesia the safest subject known to us. We know, also, that while morphine in quarter-grain doses will stop labour, half-grain doses induce a sleep in which the pains continue; the same argument, I submit, applies to chloroform.

5. The discussion at the Annual Representative Meeting on the special committee's report (*Supplement*, August 2nd, p. 88) raises an analogous point, hinting that chloroform anaesthesia may predispose towards "instrumental delivery at too early a stage." That observation may be connoted with the dictum of Drs. Bourne and Burn that "the reduction in the efficiency of the contraction which it [chloroform] causes is often of benefit in avoiding perineal tears." Both suggestions imply the use of chloroform in inadequate doses. Given adequately, labour continues and the doctor is not tempted to resort to forceps sooner than he should. Pituitary extract acts normally in the deepest anaesthesia. Chloroform will not work miracles, except in an occasional neurotic case, but it gives oblivion to tortured women, enables the doctor to use his judgement in peace, and, even after a prolonged deep anaesthesia, the patient awakes astonishingly fresh.

6. Finally, I should like to suggest that this deep anaesthesia permits such freedom in manipulation that its general adoption would wipe out many vexed questions of "difficult labour," and render obsolete whole chapters and books on the subject.—I am, etc.,

Belfast, Aug 11th. ROBERT WATSON.

X-RAY TREATMENT OF TONSILS.

SIR,—In reply to Dr. Webster's letter of August 9th (p. 228) I would point out that in his original letter of February 1st he suggested radiation weekly up to 4H with 4 mm. Al filter. By June 28th (p. 1197) this has become "50 per cent. or less of the erythema dose with a 4 mm. Al filter fortnightly." In the confusion I have been guilty of misquoting the time period; however, I rather gather that Dr. Webster prefers to remain indefinite about his dosage, especially as to whether the tonsils themselves are to receive 50 per cent of an erythema dose even fortnightly.

In connexion with my objection to the secondary radiation of the thyroid and accessory structures, I am very surprised that Dr. Webster has not found cases of injury to tissue caused by repeated diagnostic exposures. I have seen several cases of baldness following the over-enthusiastic x-ray examination of sinuses, and I know other workers who have also had similar experiences. Regarding the pathological argument, Dr. Webster in the *Journal* of June 28th stated that haemolytic streptococci in tonsillar crypts were probably not malign, rather the contrary, as these organisms were essential factors in the normal antibody laboratory. He now changes his ground to an argument that the reticulo-endothelial system as a whole forms antibodies; this proposition, so far as I am aware, is pretty generally agreed upon; but surely the tonsils form a very small part of this vast system. May I repeat that I cannot agree that haemolytic streptococci are beneficial to the

Obituary.

HUGH SMITH, M.D., F.R.C.S.,

Consulting Physician, Somerset Hospital, Cape Town.

We regret to have to record the death of Dr. Hugh Smith, which took place at his home in Cape Town on July 2nd.

Hugh Smith, who was born in London in 1863, received his early education at the City of London School, subsequently entering the London Hospital after winning an entrance scholarship. In 1886 he obtained the diploma M.R.C.S., and in the following year he graduated M.B.Lond. with first-class honours in medicine; he proceeded M.D. in 1889, in which year he also became a Fellow of the Royal College of Surgeons. After holding several resident appointments, among them that of house-physician to Hughlings Jackson, he commenced general practice in North London in 1891, remaining there until 1900, when he went to Cape Town to join the late Sir Alfred Thompson in partnership. In 1902 he became honorary physician to the Somerset Hospital at Cape Town, and was appointed consulting physician on his retirement from this post in 1919. During the war he was consulting physician to the military hospitals at Wynberg and Maitland. Until the time of his death he was lecturer in dermatology in the faculty of medicine of the University of Cape Town, and during the greater part of his professional life in that city he was also consulting dermatologist to the Somerset Hospital.

Dr. Hugh Smith was recognized as a reliable and careful physician, imbued with the highest ideals of his profession, and devoted to the service of his colleagues and the public. He was an active member of the British Medical Association, holding office as president of the Cape of Good Hope (West) Branch in 1914, and being a member of the Branch Council from 1915 to 1925. He was also president of the medical congress which met at Cape Town in 1921, and served on the South African Committee of the British Medical Association. His publications included articles on cerebral tumours. He is survived by his widow.

Dr. WILLIAM CRAIG was the senior medical practitioner and one of the most prominent citizens in the town of Cowdenbeath, Fife, where his death took place on August 14th. A native of Dumfries, he graduated M.B., C.M. at the University of Edinburgh in 1886, proceeding M.D. in 1900. In addition to conducting a busy practice, he had held the position of medical officer of the burgh for the long period of thirty-seven years. In all activities promoted for the welfare of the district he took an active part, and among the many institutions which benefited by his guidance and help were the literary society, the golf club, the angling club, and the curling club. He was also prominently identified with Beath parish church. Dr. Craig is survived by a widow and a family of three, one of whom is a member of the medical profession.

Dr. FREDERICK GEORGE LLOYD of Oakwood Court, Kensington, who died on August 6th, in his sixty-sixth year, was educated at St. Bartholomew's Hospital, and became M.R.C.S., L.R.C.P. in 1892. He was subsequently resident medical officer at the West London Hospital. In 1896 he was in medical charge of the transport *Harlech Castle*, which brought back many of those who had taken part in the Jameson raid. During the Boer war he was for some time attached as surgeon to the Brigade of Guards Hospital, London, and afterwards served as a civil surgeon in H.M. Field Force, receiving the medal and clasps. During the more recent war Dr. Lloyd served at home, and was for a time in medical charge of the late Lord Dunraven's yacht *Grianaig*, which was used as a hospital ship. A regular attendant at the meetings of the West London Medico-Chirurgical Society, of which he had been a member since 1902, he was for some time on the council, and also a vice-president, reading papers from time to time. In the session of 1920–21 he opened a discussion on the interim report of the Consultative Council of the Ministry of Health on Medical and Allied Services. He also took a keen interest in the voluntary hospital question, and spoke on it frequently in various places. He was very popular with his patients and colleagues.

Dr. JAMES BURNETT LAWSON, who died at Rothesay on August 9th, at the age of 71, was a well-known figure throughout the West of Scotland. He was a graduate of Glasgow University, where he received the degrees of M.B., C.M. in 1883 and of M.D. in 1886. Soon after graduation he built up a large practice in Rothesay, from which he retired some time ago on account of ill-health. For many years he held the offices of medical officer of Rothesay parish and of Bute schools; he was also medical officer to the Admiralty. He was a justice of the peace, president of Bute Benevolent Society, and for some time a member of the town council. Only a few weeks ago he received a public testimonial in recognition of his services. Dr. Lawson was possessed of much literary ability; his writings include *Glimpses of Rothesay and its People Fifty Years Ago* and *A Cameronian Officer*, the latter a memoir of his son, Lieutenant James B. Lawson, who was killed in the war. He contributed articles on "Phthisis pulmonalis with emphysema" to the *Glasgow Medical Journal* in 1890, and on "A general practitioner's experience of lunacy certification" to the *Practitioner* in 1925. Dr. Lawson is survived by his wife, two sons, and two daughters.

Dr. JOHN HUMPHRY WILLIAMS, J.P., who died on August 17th, at the age of 72, had practised in Flint during the greater part of his life. He received his medical education at Edinburgh, where he graduated M.B., C.M. in 1881, and proceeded M.D. five years later. He was medical officer of health for the borough of Flint, Connah's Quay Urban District, and Chester Port, and honorary surgeon to Flint Cottage Hospital. He held a commission in the R.A.M.C.(T.). He was a member of the British Medical Association, and was chairman of the Denbigh and Flint Division in 1922, he served on the executive committee in 1928. A colleague writes: Dr. Williams was a prominent member of and a regular attendant at, meetings of the British Medical Association and of the local panel committee. As "Father" of the Flintshire County Council, he was prominent on the Liberal side, enjoying debates, politics, hard-fought elections, and platform speaking. He was a particularly well-read man, fluent in two languages. As a physician he was excellent and most hard-working, snatching his recreation in the form of public work. Dr. Williams was highly respected and beloved by his colleagues, patients, and political opponents, by reason of his blunt honesty and kindness of heart. He leaves a widow, daughter, and two sons.

The following well-known foreign medical men have recently died: Dr. C. LENORMANT, professor of surgical pathology in the Paris faculty of medicine; Dr. HANS KNORR, professor of orthopaedics and head of the orthopaedic clinic at Heidelberg; Dr. JULIUS RAECKE, a Frankfurt psychiatrist; Geheimrat Dr. PAUL KRASKE, Pro-emeritus professor of surgery at Freiburg, aged 80, Professor SIEGFRIED KAMINER, co-founder with Professor Senator and for many years editor of the *Zeitschrift fur Balneologie* and *Jahrbucher fur Balneologie*, aged 57; Professor LUDWIG REIN, an eminent Frankfurt surgeon; Dr. EDMUND HERRMANN, an obstetrician and gynaecologist of Vienna, aged 55, Professor LOUIS BOX, professor of anatomy and formerly rector of the University of Amsterdam, aged 64, Dr EMIL REDLICH, extraordinary professor of neurology and psychiatry at Vienna, aged 64; Dr. ERNEST CONSEIL, director of the Tunis bureau of hygiene, and a collaborator of Dr. Charles Nicolle of the Pasteur Institute of Tunis, and Dr. Lalanne, an alienist of Nancy.

Universities and Colleges.

UNIVERSITY OF LONDON.

Applications for the William Julius Mickle Fellowship must be sent in before October 1st. Full particulars can be obtained from the Academic Registrar, University of London, South Kensington, S.W.7. The Fellowship, which is of the value of at least £230, is awarded to the man or woman who, being resident in London and a graduate of the University, has, in the opinion of the Senate, done most to advance medical art and science during the preceding five years.

University College Hospital Medical School.

The Goldsmid Entrance Exhibitions for 1930 have been awarded to Mr. G. Quist and Miss M. H. James of University College, London.

UNIVERSITY OF ABERDEEN.

Dr. David Campbell, Pollok Lecturer in pharmacology and therapeutics in the University of Glasgow, has been appointed Regius professor of materia medica in the University of Aberdeen, in succession to Professor Charles Robertshaw Marshall, whose resignation takes place on September 30th.

SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have passed in the subjects indicated:

Surgery.—G. P. Charles, H. G. Edmunds, C. W. Ellison, E. J. Jones, N. I. Kronenberg, W. Montgomery Smith, H. I. Newman, R. D. Newton, K. V. Pillai, L. Sachs, I. J. Todd-Naylor, G. H. C. Walmsley.

Medicine.—H. W. E. Dickey, E. A. Freywith, N. I. Kronenberg, J. M. L. Love, W. Montgomery Smith, H. I. Newman, I. J. Todd-Naylor.

Forensic Medicine.—M. M. Barritt, J. S. P. Coutts, C. R. Graham, M. Halperine, N. I. Kronenberg, W. Montgomery Smith, H. I. Newman, W. K. Schnaar, G. H. G. Walmsley, I. M. Williams.

Midwifery.—S. Gurevich, M. Halperine, E. I. B. Hawes, W. Montgomery Smith, W. W. Parry.

The diploma of the Society has been granted to Messrs. M. M. Barritt, G. P. Charles, H. W. E. Dickey, H. G. Edmunds, C. W. Ellison, E. A. Freywith, N. I. Kronenberg, W. Montgomery Smith, I. J. Todd-Naylor, G. H. C. Walmsley.

Medical News.

The University of Birmingham will celebrate, on October 13th, the jubilee of the foundation of Mason College and the thirtieth anniversary of the granting of the University charter.

St. Bartholomew's Hospital old students' annual dinner will be held on Wednesday, October 1st, at 7.30 p.m., in the great hall of the hospital, with Mr. L. B. Rawling in the chair. The honorary secretary is Sir Charles Gordon-Watson, 82, Harley Street, W.1.

The St. Thomas's Hospital old students' dinner will take place at St. Thomas's House, Lambeth Palace Road, S.E.1, on Friday, October 3rd, at 7.30 for 8 p.m. The chair will be taken by Dr. R. Muzio Williams, J.P.

The opening ceremony of the winter session of the Middlesex Hospital Medical School will take place at the Queen's Hall, Langham Place, W.1, on October 1st, at 3 p.m. The prizes and medals gained by students and nurses during the past year will be given away by Mr. Arthur Greenwood, M.P., Minister of Health, and the introductory address will be delivered by Mr. Eric Pearce Gould, M.Ch., F.R.C.S. The hospital and medical school will be open for inspection after the ceremony, and tea will be provided. The annual dinner of past and present students of the hospital will be held at the Savoy Hotel in the evening.

The annual dinner of past and present students of St. Mary's Hospital Medical School will be held at the Trocadero Restaurant on Friday, October 3rd, at 7 p.m., with Dr. J. Reginald Fuller in the chair.

The prize distribution and conversazione of the Royal Dental Hospital of London School of Dental Surgery will be held at the hospital, Leicester Square, W.C., on Thursday, October 2nd, at 8 p.m. Sir John Rose Bradford, P.R.C.P., will preside.

Under the auspices of the National Association for the Prevention of Infant Mortality a special course of maternity and child welfare lectures will be held for health visitors, nurses, midwives, school teachers, and welfare workers in the lecture theatre of University College, Nottingham, from September 15th to 19th. In conjunction with this course visits will be paid to various institutions; arrangements for board and lodging in Nottingham will be made on application before September 1st to the secretary, Health Department, Guildhall, Nottingham. Further details of the course may be obtained from the honorary secretary of the National Association, Carnegie House, 117, Piccadilly, W.1.

The new session of the Medical Society of London commences on Monday, October 13th, when the annual general meeting will be held at 8 p.m. At 8.30 p.m. Dr. R. A. Young will deliver his presidential address on "The stethoscope—past and present." On October 27th, at 8.30 p.m., a discussion entitled "The prophylactic and therapeutic values of vaccines" will be introduced by Sir Almroth Wright. Professor Chevalier Jackson will open a discussion, on November 10th, on the diagnosis and treatment of malignant disease of the chest. The Lloyd Roberts Lecture on "Painting and the healing art" will be delivered by Professor William Rothenstein on Wednesday, November 19th, at 5 p.m. A clinical evening will be held on November 24th, at 8 o'clock, and on Monday, December 8th, a discussion on pathological conditions of the eye due to inflammatory changes in other parts of the body will be introduced by Mr. A. F. MacCallan, F.R.C.S., followed by Mr. Ernest Clarke, F.R.C.S. The syllabus of the second half of the session will be issued in December. The Lettsomian Lectures, entitled "The spleen—its structure, functions, and diseases," will be delivered by Dr. J. W. McNee on February 16th and 25th, and March 4th, 1931. Sir John Rose Bradford, P.R.C.P., will give the annual oration on Monday, May 11th, 1931.

The Fellowship of Medicine announces that from September 1st to 13th there will be an all-day course at the Queen's Hospital for Children, when instruction will be given in the various departments of the institution. A revision course, particularly of interest to panel practitioners, will be conducted at the Westminster Hospital from September 15th to 27th; the daily sessions will begin at 10.30 in the morning and continue until 5.30 p.m. All branches of medicine and surgery will be dealt with, and two clinics will be held on the Saturday mornings at mental institutions connected with the hospital. A revision course will also be held at the Metropolitan Hospital from September 29th to October 11th, of a similar nature to that at the Westminster Hospital. An intensive course at the Central London Throat, Nose and Ear Hospital from October 5th to November 1st will be preceded by a course in "methods of examination," starting on September 17th; applications should be made to the Fellowship of Medicine. The subjects of other courses in October are tropical medicine and gynaecology; there will be two evening courses at 8.30—a M.R.C.P. course and a final Fellowship course. For full particulars of the post-graduate study arranged for the winter session, also for the 1931 list of special courses and the *Post-Graduate Medical Journal*, application should be made to the secretary of the Fellowship, 1, Wimpole Street, W.1.

The annual meeting of the German Society for Light Research will be held in conjunction with the German Hygiene Society at Dresden on September 5th and 6th.

An elementary practical course in diseases of the digestive system, organized by Professor F. Gallart, assisted by other members of the medical faculty of Barcelona, will be held at the Hospital de la Santa Cruz y San Pablo, Barcelona, from October 12th to 20th. The fee is 100 pesetas.

The seventeenth French Congress of Hygiene will be held at the Institut Pasteur, Paris, under the presidency of Professor Delépine of the Académie de Médecine, from October 20th to 23rd, when the following subjects will be discussed: the successive changes in the French pharmacopoeias, introduced by the President; comparative statistics of infantile mortality, introduced by Dr. Lesage; the relation of health offices to health inspection, introduced by MM. Aublant and Prunet, and Brocquin-Lacombe and Bennet; and hygiene and reconstruction in the flooded area in the South of France. Lectures will also be delivered by Professor Sacquépée on psittacosis, and by Dr. Dujarric de la Rivière on Lavoisier as hygienist. Further information can be obtained from Dr. Dujarric de la Rivière, Institut Pasteur, Rue Dotot, Paris, XVe.

The twentieth Congress of the Italian Society of Laryngology, Otology, and Rhinology will be held in Sardinia from October 15th to 23rd. Further information can be obtained from Professor Deodato De Carli, Clinica Oto-rino-laringologica, Ospedale Gesu e Maria, Naples.

The thirtieth French Congress of Urology will be held at the Paris Faculty of Medicine, under the presidency of Dr. Chevassu of Paris, on October 7th, when a discussion will be held on renal contusions and their remote sequels, introduced by Dr. Gérard of Lille. Further information can be obtained from Dr. P. Pasteau, 13 Avenue de Villars, Paris, VIIe.

Lieut.-Colonel C. T. Samman has been re-elected Master of the Society of Apothecaries.

Dr. Josef Jadassohn, professor of dermatology at Breslau, has been invited by the Government of Uruguay to be president of the South American Conference on Syphilis at Montevideo in September.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9951, 9952, 9953,* and *9954* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL, Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediocrity Westcent, London.*

The address of the Irish Office of the British Medical Association is 15, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

LIMITATION OF THE GROWTH OF HAIR.

"R. D. M." asks for information about any known factor which limits the growth of hair in some situations, such as the eyebrows and eyelashes, to a certain definite length, whereas in other situations, such as the scalp and face, the growth of hair is continuous.

TREATMENT OF DYSMENORRHOEA.

DR. JOHN R. KEITH (Southend), replying to Dr. E. R. B. Murray's inquiry (August 16th, p. 272), writes in the course of a letter: In certain conditions, among them dysmenorrhoea, beneficial results may be obtained by applying counter-irritation over the spinal cord. In cases of dysmenorrhoea a cantharides blister may be applied over that part of the cord which is covered by the bodies of the fourth and fifth dorsal vertebrae, and kept in position for three or four days before the expected period. In many cases of painful menstruation points of tenderness may be found to the right or left of one or more of the first four lumbar spines. If firm pressure is made over these sensitive areas the menstrual pain will disappear for several hours or during the whole period. Freezing the tender areas with ethyl chloride or petroleum ether is even more effective.

DR. N. HAIER (London, W.1) writes: In reply to Dr. Murray's inquiry (August 16th, p. 272), I would suggest the use of an intra-uterine silver ring. This instrument was first devised as a contraceptive, but I have noticed that several patients have been partly or entirely freed from dysmenorrhoea after its insertion.

KEEPING FIT IN HOT CLIMATES.

DR. O. MARRIOTT (Haywards Heath), replying to the inquiry of "C. H. B." in the *Journal* of July 26th (p. 168) writes: After twenty years' actual busy practice in the Tropics, I am of opinion that it is not advisable, and certainly not necessary, to take alcohol in any form in hot climates; I will even go further and say that, in my opinion, a "worker" (mental or physical) is better and more efficient without alcohol under tropical conditions. Several men who have lived successful lives in tropical countries, following such advice given them by me from early days, have taken the trouble to come to thank me for it, having found it so much to their advantage in health and fitness. It is certainly advisable to have always some light thin covering round the abdomen while in bed at night, such as a light tropical weight viyella blanket wrapped round once. Exercise, like all other things in the Tropics, should be taken in moderation. Under true tropical conditions a man can get his skin to act as much as is convenient or healthy—or more so—in his ordinary routine, unless he spends his days under a fan in a club armchair; strenuous physical exercise daily is apt to take too much out of him to permit his carrying on his routine daily work efficiently. Personally, I never touched alcohol during twenty years' hard work in the Tropics, and I always slept with a light blanket round the abdomen, or, if such was not available, used an ordinary "bath" towel as a wrap. With the exception of occasional swimming during my earlier years in the Tropics, I never had any time for strenuous physical exercise, but I obtained all the perspiration I cared for—and generally more—by carrying on my active professional life. I found it a relief at times to slip into my quarters and to strip from clothes wet through with perspiration, have a good warm bath, and a change of clothing.

LETTERS, NOTES, ETC.

THE MEDICAL RESEARCH COUNCIL AND ERGOT STANDARDIZATION.

WE have received the following communication from the manager of "Sandoz" Scientific and Research Department, Wigmore Street, W.:

"In your last issue you give prominence to an official statement by the Medical Research Council under the title 'The Medical Research Council and Ergot Standardization.' The Medical Research Council complain that misuse has been made of their name in literature issued to the medical profession in America by our American house, Sandoz Chemical Works, Inc., of New York. The statement complained of reads as follows: 'The Pharmaceutical Society of Great Britain, after consultation with the Medical Research Council, adopted Gynergen as the standard for ergot.' I am directed by Sandoz Chemical Works, Basle, to request the courtesy of your columns to reply to the communication of the Medical Research Council. To our great regret the official statement of the Medical Research Council is presented in such a manner that it fails to reveal the whole truth. It should be made clear that Gynergen is ergotamine tartrate, and that there is only one ergotamine—Ergotamine, Stoll-Sandoz. The following extract is taken from the *Pharmaceutical Journal* of February 20th, 1926:

> 'Pharmaceutical Society of Great Britain: The Pharmacological Laboratories.
>
> '(Text of a pamphlet which is being supplied to inquirers by the Secretary of the Society, 17, Bloomsbury Square, London, W.C.1.)
>
> 'These laboratories are now in a position to test the drugs and preparations dealt with in detail hereafter.
>
> '3. Ergot.—Samples of ergot will be accepted to be tested in the form of the powdered ergot. The Geneva Conference has made no recommendations in the matter of ergot. The chief active substances which may be present in extracts are ergotamine (or ergotoxin), histamine, and tyramine. It will be assumed that the therapeutically active substance is the specific alkaloid ergotamine, and a test for its amount will be applied to an acid alcoholic extract of the powdered drug.
>
> 'As standard a sample of ergotamine tartrate is available, prepared by the Sandoz Chemical Works, Basle.
>
> 'The test applied will be the capacity of an acid alcoholic extract prepared from the sample to reverse the action of adrenaline either on the blood pressure of a pithed cat or on the isolated uterus of the rabbit. After consultation with the Director of the Department of Biological Standards, Medical Research Council, it has been decided to approve as good samples of ergot those containing not less than 1 mgm. per gram of the specific alkaloid.'

"Further, in the *Pharmaceutical Journal* of March 13th, 1926, the following appeared:

> 'In the number of this Journal published on February 20th last a description appeared of the tests which these laboratories are prepared to carry out. When a preparation has been tested, a certificate is issued, which in the case of satisfactory preparations may be used by the maker as the basis of a statement on the label. . . . The statement appearing on the label must be confined to the words . . . .'
>
> '(6) In the case of ergot preparations . . . one of this preparation contains 1 mgm. ergotamine as determined by a biological test carried out by the Pharmaceutical Society of Great Britain.'

"To make the matter more clear we quote from the *Pharmaceutical Journal* of May 14th, 1927, where the Director of the Pharmacological Laboratories, replying to Mr. A. O. Bentley, stated: 'There has been no ergotoxine in this country since the war until a month or two ago.' The reasons which caused the substitution of an amorphous alkaloidal salt, difficult to purify, of lesser stability, less soluble, and which can only be conserved with difficulty *in vacuo* over phosphorus pentoxide, for a definite, pure, stable, crystalline substance (base as well as salt) is probably not relevant here, but it is clear that ergotamine tartrate *was* adopted as the standard for ergot preparations, and that the Medical Research Council *was* consulted and that the statement by the Medical Research Council is equivocal."

INFECTED EGGS.

MR. J. G. MAYNARD (Somerset), in the course of a letter on behalf of the council of the Utility Duck Club, writes: In the *British Medical Journal* of July 12th (p. 56) an article appeared by Dr. W. M. Scott on food poisoning due to eggs; unfortunately this article has been taken up by the popular press, with disastrous results to producers in this country. The council of the Utility Duck Club does not dispute the evidence brought forward in the article; it does, however, wish to draw attention to the fact that very large numbers of ducks' eggs are imported every year. The conditions under which these are produced are frequently unsanitary, the ducks being kept in large numbers on foul ground where they are fed on fish which is often far from fresh. The resultant disease among the flocks is amply attested. It may safely be stated that such diseases are almost entirely unknown among English birds. When cases of poisoning have occurred the club has tried to trace the origin of the eggs, and in no case of which the council knows have the eggs been produced in this country. All imported eggs have now to be marked with the stamp of country of origin, so that it is possible to avoid imported supplies.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 35, 36, 37, 38, 39, 42, 43, and 44 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 40 and 41.

A short summary of vacant posts notified in the advertisement columns appears on page 340.

VACANCIES.

All Saints Hospital for Genito-Urinary Diseases.—House-Surgeon (male). Salary £150 per annum.

Argyll County Council.—Medical Officer for the District of Glenorchy. Salary includes payment of £125 per annum for services as Local Medical Officer and a grant from the Highlands and Islands (Medical Services) Fund.

Bangour Mental Hospital, West Lothian.—Second Assistant Medical Officer. Salary £350 per annum, rising to £400.

Barnstaple: North Devon Infirmary.—Resident Medical Officer. Salary £150 per annum.

Barrow-in-Furness: North Lonsdale Hospital.—Two House-Surgeons (males). Salary £175 per annum.

Bath: Royal United Hospital.—Assistant House-Surgeon (male, unmarried). Salary £120 per annum.

Bedford County Hospital.—House-Surgeon (male, unmarried). Salary £175 per annum.

Birkenhead General Hospital.—(1) House-Physician. (2) Casualty Officer. Males. Salary £100 per annum each.

Birmingham and Midland Skin Hospital.—*Clinical Assistants in the Out-patient Consulting Room* Honorarium 26 guineas per annum.

Bournemouth: Royal Victoria and West Hants Hospital.—House-Surgeon (male) at Boscombe Branch. Salary £150 per annum.

Brighton: Royal Sussex County Hospital.—*Casualty* House-Surgeon (male, unmarried). Salary £120 per annum.

Bristol Royal Infirmary.—Assistant for Cancer Research Laboratories. *Salary £400 per annum.*

Burslem: Haywood Hospital.—Resident Medical Officer. Salary £175 per annum.

Cardiff City Mental Hospital, Whitchurch.—Post-graduate Research Studentship. Honorarium £100 per annum, augmented by locum work in the Hospital to approximately £180.

Central London Throat, Nose and Ear Hospital, Gray's Inn Road, W.C.1. —*Honorary Assistant Anaesthetist.*

Chichester: Royal West Sussex Hospital.—Junior House-Surgeon. Salary £125 per annum.

Derbyshire Hospital for Sick Children.—Resident Medical Officer (lady). Salary £150 per annum.

Derbyshire Hospital for Women.—House-Surgeon. Salary £150 per annum.

Durham County and Sunderland Eye Infirmary.—Clinical Assistant in Out-patient Department. Salary £250 per annum.

Eastbourne: Princess Alice Memorial Hospital.—*House-Surgeon (male).* Salary £100 per annum.

Edinburgh: Jordanburn Nerve Hospital, Morningside.—Assistant Physician. Salary £400 per annum.

Essex County Hospital, Colchester.—(1) Assistant House-Surgeon and *Registrar. (2) House-Physician. Males. Salary £120 and £150 per annum respectively.*

Gloucestershire Royal Infirmary and Eye Institution.—(1) House-Physician. (2) Second House-Surgeon. Salary £150 and £120 per annum respectively.

Great Yarmouth: General Hospital.—*Two House-Surgeons, Senior and* Junior. Salary £150 and £140 per annum respectively.

Halifax: Royal Halifax Infirmary.—Third House-Surgeon (male, unmarried). Salary £125 per annum.

Hostel of St. Luke, 14, Fitzroy Square, W.1.—Resident Medical Officer. Salary £200 per annum.

Hull Royal Infirmary.—Honorary Physician.

Ilford: King George Hospital.—Resident Medical Officer. Salary £200 per annum.

Ipswich: East Suffolk and Ipswich Hospital.—*(1) Casualty Officer.* (2) House-Surgeon. Males. Salary £150 and £120 per annum respectively.

Leeds Public Dispensary.—Junior Resident Medical Officer. Salary £150 per annum.

Leicester Royal Infirmary.—(1) House-Surgeons. (2) Casualty Officer. Salary £125 per annum each.

Liverpool and District Hospital for Diseases of the Heart.—House-*Physician. Salary £52 per annum.*

Liverpool Eye and Ear Infirmary.—Honorary Assistant Surgeon to the Ear, Nose, and Throat Department.

London Female Lock Hospital, 283, Harrow Road, W.9.—House-Surgeon. Salary £150 per annum.

London Lock Hospital, 91, Dean Street, W.—(1) Surgical Registrar. (2) Additional Surgical Registrar. (3) House-Surgeon at Male Lock Hospital. Honorarium for (1) and (2) £100, for (3) £200 per annum.

Lowestoft and North Suffolk Hospital.—*Junior House-Surgeon (male).* Salary £120 per annum.

Macclesfield General Infirmary.—Resident House-Surgeon. Salary £180 per annum.

Manchester: Ancoats Hospital.—House-Surgeon (male). Salary £100 per annum.

Manchester City.—Assistant Medical Officer at Baguley Sanatorium. Salary £350 per annum.

Manchester: Royal Manchester Children's Hospital.—*(1) Resident* Medical Officer. (2) Resident Surgical Officer. (3) Two Assistant Medical Officers for Out-patients' Department. Salary for (1) and (2) £125 per annum, and for (3) £150 per annum.

Manchester and Salford Hospital for Skin Diseases.—House-Surgeon. Salary £100 per annum.

Manchester University.—Demonstrator in Chemical Pathology. Stipend £350 per annum.

Manchester University and Manchester Committee on Cancer.—Assistant in the Cancer Research Laboratories. Salary £400 to £650 per annum.

Mansfield and District Hospital.—House-Surgeon and Casualty Officer (male). Salary £150 per annum.

Middlesbrough: North Riding Infirmary.—Junior House-Surgeon (male). Salary £150 per annum.

Middlesex County Council.—Resident Medical Officer (male) at Hillingdon Institution, Uxbridge. Salary £600 per annum.

Middlesex Hospital, W.1.—Dental House Surgeon.

Middlesex Hospital Medical School, W.1.—Assistant in Radiological Research bearing upon the treatment of *malignant* disease. Salary £350 per annum.

Miller General Hospital, Greenwich Road, S.E.10.—(1) Casualty Officer. (2) House-Physician. (3) House-Surgeon. Salary for (1) £150, and for (2) *and (3) £125 per annum.*

National Hospital for Diseases of the Heart, Westmoreland Street, W.1.—(1) Resident Medical Officer. (2) Out-patient Medical Officer. Males. Salary £150 and £125 per annum respectively.

Northampton General Hospital.—(1) House-Physician. (2) Two House-Surgeons. (3) Two Assistant House-Surgeons. Salary £150 per annum.

Northern Ireland Government.—Medical Officer. Salary £800-£25-£1,000, *plus* bonus.

Nottingham General Hospital.—(1) House-Physician. (2) Second Casualty Officer *(male)* Salary £150 per annum each.

Oldham Royal Infirmary.—Two House-Surgeons. Salary £175 per annum.

Oldham County Borough.—Female Assistant Resident Medical Officer (unmarried) at the Boundary Park Municipal Hospital. Salary £200 per annum.

Oxford: Radcliffe Infirmary and County Hospital.—(1) Three House-Surgeons. *(2) House-Physician. (3) Obstetric House-Physician.* Salary £120 per annum.

Poole: Cornelia and East Dorset Hospital.—House-Surgeon (male). *Salary £150 per annum.*

Princess Louise Kensington Hospital for Children, W.10.—House-Surgeon and Casualty Officer. Salary £75 per annum, rising to £100 on appointment as Senior Resident.

Queen Charlotte's Maternity Hospital, Marylebone Road, N.W.1.—(1) Assistant Resident Medical Officer. (2) Resident Anaesthetist. Salary for (1) £80 per annum, rising to £100 on appointment as Senior, and for (2) £80 per annum.

Queen's Hospital for Children, Hackney Road, E.2.—Casualty Officer. *Salary £100 per annum.*

Royal Eye Hospital, St. George's Circus, S.E.1.—(1) Twelve Salaried Refractionists. (2) Twelve Clinical Assistants. (3) Pathologist.

Royal National Orthopaedic Hospital, Great Portland Street, W.1.—House-Surgeon (male). Salary £150 per annum.

Ryde: Royal Isle of Wight County Hospital.—(1) Member of Honorary Medical Staff. (2) Resident House-Surgeon, salary £180 per annum.

St. John's Hospital, Lewisham, S.E.13.—Resident Casualty Officer. Salary £100 per annum.

St. Paul's Hospital for Genito-Urinary Diseases, Endell Street, W.C.2.—(1) Resident Medical Officer. (2) House-Surgeon. Salary £200 and £150 per annum respectively.

St. Vincent's Orthopaedic Hospital, Eastcote.—Resident Medical Officer (unmarried). *Salary £150 per annum.*

Salford Royal Hospital.—(1) House-Surgeon attached to the Orthopaedic Department. (2) House-Surgeon. Salary £125 per annum each.

Seamen's Hospital Society.—(1) Two House-Physicians at the Hospital for Tropical Diseases, Endsleigh Gardens, W.C. (2) House-Physician and House-Surgeon at Dreadnought Hospital, Greenwich. (3) Medical *Officer at Albert Dock Hospital. (4) House-Surgeon at Tilbury* Hospital. Males. Salary for (1) and (4) £150, and for (2) and (3) £110 and a proportion of fees.

Sheffield Royal Hospital.—Resident Anaesthetist (male). Salary £80 per annum, rising to £100 after six months.

Shrewsbury: Eye, Ear, and Throat Hospital for Shropshire and Wales. —House-Surgeon (unmarried). Salary £200 per annum.

South Shields: Ingham Infirmary.—Junior House-Surgeon (male). Salary £150 per annum.

Staffordshire General Infirmary.—(1) House-Surgeon. (2) House-Physician. Salary £200 and £150 per annum respectively.

Stockton and Thornaby Hospital, *Stockton-on-Tees.—Junior Resident* Medical Officer (male). Salary £150.

Stoke-on-Trent: North Staffordshire Royal Infirmary.—Assistant House-Physician. Salary £125 per annum.

Swansea Hospital.—House-Surgeon (male, unmarried). Salary £150 per annum.

Tynemouth County Borough.—Assistant Medical Officer of Health (male). Salary £540 per annum.

Walsall County Borough.—First Assistant Resident Medical Officer at Manor Hospital. Salary £200 per annum.

West Bromwich and District General Hospital.—(1) House-Physician. (2) Casualty House-Surgeon. Males, unmarried. Salary £200 per annum.

West Hartlepool: Cameron Hospital.—*House-Surgeon. Salary £150 per* annum.

West London Hospital, Hammersmith Road, W.6.—(1) House-Physician. (2) Two House-Surgeons (males). (3) Resident Anaesthetist. Salary *£100 per annum.*

West Norfolk and King's Lynn Hospital.—(1) Senior House-Surgeon. (2) Junior House-Surgeon. Salary £150 and £100 per annum respectively.

Willesden Urban District Council.—Resident Medical Officer at the Willesden Municipal Hospital. Salary £250 per annum.

Wolverhampton and Midland Counties Eye Infirmary.—House-Surgeon. Salary £150 per annum.

Woolwich and District War Memorial Hospital, S.E.18.—House-Surgeon. Honorarium £100 per annum.

York: County Hospital.—House-Physician. Salary £150 per annum.

Certifying Factory Surgeons.—The following appointments are vacant: Llanybyther (Carmarthenshire); Paisley (Renfrewshire). Applications to the Chief Inspector of Factories, Home Office, Whitehall, S.W.1.

This list of vacancies is compiled from our advertisement columns, where full particulars will be found. To ensure notice in this column advertisements must be received not later than the first post on Tuesday morning.

POST-GRADUATE COURSES AND LECTURES.

Fellowship of Medicine and Post-Graduate Medical Association.—*Queen's Hospital for Children*, Hackney Road, E.2: Special Course, all day. Fee £2 12s. 6d. for two weeks. Syllabus and ticket of admission from the Fellowship of Medicine, 1, Wimpole Street, W.1.

Central London Throat, Nose and Ear Hospital, Gray's Inn Road, W.C.1. —Fri., 4 p.m., Acute Mastoiditis.

Liverpool University Clinical School Ante-Natal Clinics.—Royal Infirmary: Mon. and Thurs., 10.30 a.m. Maternity Hospital: Mon., Tues., Wed., Thurs., and Fri., 11.30 a.m.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcement of Births, Marriages, and Deaths is 9s., which sum should be forwarded with the notice not later than the first post on Tuesday morning, in order to ensure insertion in the current issue.

MARRIAGES.

Anderson—Hytch.—At St. George's Church, Bloomsbury, on June 21st, 1930, by the Rev. W. C. Roberts, M.A., Rupert George Anderson, M.B., Ch.B.Ed., D.P.H.Lond., only son of the late D. L. Anderson, C.A., F.F.A., Glasgow, and of Mrs. Anderson of London, to Dorothy Preston Hytch, M.R.C.S.Eng., L.R.C.P.Lond., only daughter of Mr. and Mrs. E. Preston Hytch of Normandy, Surrey.

Gedye—Locke.—On August 20th, at St. Paul's Church, Clifton, Bristol, Francis Ronald Gedye, M.B., Ch.B., son of the late Rev. E. F. Gedye, to Doris Kathleen Locke, daughter of Mr. and Mrs. T. W. Locke of Redland, Bristol.

Mackintosh—Haworth.—On August 25th, 1930, at Christ Church, Didsbury, by the Rev. E. N. Giles, assisted by the Rev. E. R. Hayes, Vicar of Melling Church, James Mackintosh, M.C., M.R.C.V.S., of Embo, Sutherland, to Doris Adeline Haworth, M.B., Ch.B., D.P.H., widow of the late Dr. Albert Haworth, M.Sc., M.B., Ch.B.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

200. The Blood Pressure in Health.

BELIEVING that there is need for more knowledge about physiological variations in blood pressure, W. C. ALVAREZ and L. L. STANLEY (*Arch. Int. Med.*, July, 1930, p. 17) record a statistical study of the blood pressure in 6,000 prisoners and 400 prison guards. The mean pressure in the prisoners varied but little from youth to old age, and was found to be about 115 mm. of mercury. This is less than the figure usually noted for men out in the world, and its lowness is attributed to the fact that the prisoners were not fatigued, and were free from the worry of earning a living—that is, to a certain extent their pressures were basal. It appears from this study that a pressure of 115 mm. is just as normal, and a pressure of 140 mm. just as abnormal, in an old man as in a young one. After the age of 35 fatness tends to increase the blood pressure, and thinness to decrease it. No increase of pressure was found in syphilitic prisoners. Also, judging from this series, the taking of alcohol has no effect on blood pressure, but drug addicts appeared to have slightly increased pressures during middle life; the use of tobacco in young men appeared to raise the modal pressure about 4 mm., but did not produce pathological hypertension. Cool weather slightly raised the level of mean blood pressure. The average diastolic pressure was 68.5 mm. in the younger and 73 mm. in the older men. This pressure tends to rise several years earlier than the systolic, and consequently pulse pressure decreases during the fourth decade of life. Fatness and leanness have a slight effect on diastolic pressure. In middle-aged men there was a slight correlation between the systolic pressure and the weight, and also between the systolic pressure and the surface area, but no association was traced with the height or with the degree of stockiness or ranginess. Contrary, then, to the general impression, the authors conclude that thick-set, stocky men are apparently no more likely to develop hypertension than are tall, thin, asthenic-looking individuals. The guards had pressures considerably higher than those of the prisoners; this might have been due partly to overweight and partly to the fact that when the pressures were taken these men were applicants for posts and were therefore under a certain degree of mental strain.

201. Headache at Puberty.

THE endocrine glands, chiefly the pituitary, thyroid, and suprarenals, govern the morphological and biochemical changes occurring at puberty; a disorder of these glands may cause anomalies or dysfunction of the sexual glands, or even troubles of a general order at that time. A. POPÉA and A. DIMOLESCU (*Rev. Med. Roumaine*, May–June, 1930, p. 121) state that headache is one condition often observed at puberty which has not been accorded sufficient attention. It may be diffuse, extending over the whole brain, with a slight predominance in the frontal region; continuous, with trifling variations in intensity; or persistent, with an uninterrupted duration of several weeks or even months. Insomnia is a frequent concomitant, and the patients become inattentive, often irritable, and unable to attend to their duties. Treatment on the lines indicated for migraine is inefficacious, or produces merely a transitory cessation of the pain. Chauvet has termed this syndrome hypophyseal headache. Paulian and Sedillot have shown that migrainous crises are due to hyperaemia of a pituitary gland in a state of dysfunction. By analogy with migraine the present authors believe that this same dysfunction, which they ascribe to insufficiency, is the cause of these headaches in subjects previously suffering from hypophyseal debility. At puberty the pituitary gland performs an excess of work, for which it is not yet adapted. The resulting overwork gives rise to vasomotor troubles—that is, to a vaso-dilatation of the vessels at the base and of their meningeal branches. Three cases are recorded in which, in accordance with the above pathogenic theory, hypodermic injections (8 to 10 in number) of aqueous total extracts of suprarenal and pituitary glands were administered; thyroid extract was not given, since no patient exhibited signs of thyroid disorder. Two of the patients, seen more than a year later, were completely well; in the third the headache recurred a month after a series of 8 injections, but it was definitely cured by a second series of 6 injections.

202. Early Diagnosis of Whooping-cough by the Sedimentation Rate.

F. ROHR and J. KRIEGER (*Deut. med. Woch.*, June 6th, 1930, p. 964) found that in 69 out of 82 examinations of the sedimentation rate in children suffering from whooping-cough delay occurred in spite of the fact that catarrhal processes usually cause acceleration. In the remaining 13 cases a reason for the acceleration was found in active tuberculosis (3 cases), measles (5 cases), or other febrile conditions, such as pyaemia, varicella, or otitis, while in only one case was there no explanation of the acceleration. The tendency of the blood in whooping-cough to show a delayed sedimentation rate is little, if at all, affected by the concomitant catarrh of the nasopharynx, bronchi, and ear. The rate, however, may sometimes be accelerated by highly febrile complications, but in that event the acceleration is slighter and more transient than in non-pertussis cases. In the cases, however, in which pertussis is associated with measles, the acceleration may be of longer duration. The delay may appear in the first week of the disease, and with one exception always justified an early diagnosis of measles in the present series of cases. The authors therefore recommend that this hitherto undescribed diagnostic method should receive further trial.

203. Syphilitic Aortitis.

R. FISCHER (*Wien. Klin. Woch.*, May 8th, 1930, p. 599) refers to the increasing number of cases of syphilitic mesaortitis recorded in recent years, and recognized generally as one of the most malignant diseases of the circulatory system. He has treated about fifty cases both as out-patients and in the wards, as well as a similar number of private cases. The average length of life after the disease was diagnosed was about two years. Fischer describes two cases of early pulmonary tuberculosis in which skiagrams revealed, in one case, aortic dilatation, and in the other a sacculated aneurysm; both patients had a positive Wassermann reaction. Even under early and energetic treatment cure is impossible, but the syphilitic infiltration of the media may be arrested. A great danger is that the scar tissue may invade the ostia of the coronary arteries. The author has seen serious results follow the non-specific increase of the effect of salvarsan—for example, when milk has been injected simultaneously—and death occurred in one case after stovarsol treatment. He has given iodides in many cases, but considers that their utility is doubtful, energetic neosalvarsan treatment being recommended as the most rational method.

Surgery.

204. Sarcoma of the Stomach.

D. C. BALFOUR and J. C. MCCANN (*Surg., Gynecol. and Obstet.*, June, 1930, p. 948) report an analysis of 54 cases of gastric sarcoma observed at the Mayo Clinic during the past twenty years. The diagnosis in 53 instances was made as the result of surgical intervention for gastric lesions, and in one the condition was found at necropsy. In only 4 of the series was there any history of malignancy in the family, and the incidence varied from one to six cases a year, with an average ratio of one case of sarcoma to 111 of carcinoma in a total of 4,159 cases of malignant disease of the stomach. Males predominated over females in a ratio of 25 to 1. Before the operation the average duration of symptoms was eighteen months, and these ranged from localized gastric disorders such as dyspepsia, epigastric pain, palpable tumour, haemorrhage, weakness, and vomiting, to indefinite conditions which did not point to the seat of the trouble. The majority of lesions were diagnosed as gastric carcinoma before the operation, which consisted of partial gastrectomy, and was followed by the administration of Coley's toxins and irradiation in two suitable cases, with irradiation alone in 14 cases. The authors remark that the extent of the irradiation is always an individual problem, depending upon the clinical aspects of the case. Definite results were obtained in lymphosarcoma, in which, after removal of the growth, irradiation apparently controls lymphatic extension, with improvement in subjective gastric symptoms and in the general condition. The average duration of life after resection was eleven months, but in twelve instances the average has been five years, one patient living for nine years.

treated had suffered from chronic gonorrhoea for from five months to several years, and had failed to yield to all the usual forms of treatment. Each patient had injections of silver protein twice weekly, and a total average of 12 to 14 injections. Of these twelve cases, one was completely cured, two greatly improved, while nine cases were unaffected. The author concludes that while his results were not so brilliant as those of the French authors, owing to the difficult cases which were treated by him, this method should be tried further in view of its simplicity and harmlessness.

211. Liver Treatment of Pernicious Anaemia.

M. C. RIDDLE and C. C. STURGIS (*Amer. Journ. Med. Sci.*, July, 1930, p. 1) find that in pernicious anaemia the response to liver treatment depends rather on the amount of active liver principle given during a certain period than on the amount taken each day. A similar effect is obtained by giving 30 vials of liver extract in a single dose and ten doses, each of three vials, administered at daily intervals. The rate of reticulocyte response occurs most rapidly after the administration of a large single dose; the increase commences about forty-eight hours after a large single dose of 30 vials of extract, reaches a maximum number and percentage in 104 to 140 hours, and ends after 240 hours. The stimulating effect on the bone marrow after the administration of a single dose of 30 vials of extract is indicated in the blood during the first two or three days by numerous nucleated red cells and immature white cells of myeloid origin. The reticulocyte response, the increase in the red cell count, and the amount of haemoglobin are as satisfactory after a single dose of 30 vials as when three vials, corresponding to half a pound of liver, are given daily for ten days. The effect of the large dose lasts about ten days.

Laryngology and Otology.

212. Infection of the Ear with the Streptococcus haemolyticus.

J. M. ALONSO (*Rev. de Laryngol., d'Otol. et de Rhinol.*, March 15th, 1930, p. 157) draws attention to the vast number of the strains of streptococci, and points out that while many have no place in human pathology, others, and especially the *Streptococcus haemolyticus*, are the cause of grave morbid conditions. Although at present there is no proof, he believes that scarlet fever is caused by an unknown virus, and that the *Streptococcus haemolyticus* is a secondary infection; this organism has been found by one observer in 90 per cent. of extirpated tonsils, it has also been recovered from ear infections not associated with scarlet fever, but has, however, produced similar complications. The pathological process in these ear infections is usually an otitis, associated with a necrotic type of mastoiditis, meningeal complications are common. The author strongly commends the use of anti scarlet fever serum in the treatment of these cases in addition to the usual surgical measures. The antitoxin is administered by the hypodermic route and in small doses of 2 to 4 c.cm. into the spinal theca in those cases which show meningeal symptoms. The author remarks that the value of antitoxin is not universally admitted, but he quotes cases of his own in which recovery followed the treatment even when the *Streptococcus haemolyticus* had been demonstrated in stained films of the cerebro spinal fluid. It is added that these conditions are most frequent in children with adenoids present.

213. Angioneurotic Oedema and Allied Conditions Affecting the Oesophagus.

CHEVALIER JACKSON (*Trel of Otolaryngol.*, April, 1930, p. 397) describes four rare cases of oesophageal obstruction. The first patient was a woman, aged 38, who complained of sudden difficulty in swallowing, associated with retrosternal pain and swelling of the eyelids and hands. The attack had been preceded by abdominal pain and tenesmus. There was a history of similar attacks of abdominal pain, but no previous oesophageal symptoms. X ray examination revealed that the lumen of the thoracic oesophagus was markedly narrowed, and oesophagoscopy showed the oesophagus obstructed by firm bleeding nodules, white at the centre and intensely hyperaemic at the bases. The patient received treatment; at the end of two weeks all symptoms had vanished, and a second oesophagoscopy showed the mucosa of the oesophagus normal. A diagnosis of angioneurotic oedema was made. The second patient was a woman, aged 43, with sudden dysphagia associated with a facial urticaria, there was a previous history of urticaria and asthma. Oesophagoscopy revealed the lumen of the oesophagus blocked with firm white nodular swellings of the walls. The dermal rash and symptoms of dysphagia vanished on the fourth day. A second examination of the oesophagus at the end of seven days showed it to be normal. A diagnosis of urticaria was made. In the third case, that of a boy aged 18, dysphagia followed four days after the injection of serum, it was associated with urticaria, enlargement of the glands of the neck, and joint pains. The temperature rose to 101°. The oesophagus was obstructed by firm white nodules. A second examination ten days later showed the oesophagus to be normal, and a diagnosis of serum sickness was made. The fourth case was that of a woman, aged 52, who complained of intermittent attacks of painful dysphagia. Oesophagoscopy revealed the presence of chronic oesophagitis with a small superficial ulcer in the middle, and a subsequent oesophagoscopy showed the ulcer to have healed at the end of two weeks, the patient being free from symptoms. One week later she complained of a burning pain on swallowing, and suggested that the food passed a tender spot. On oesophagoscopy there was seen a welt-like ridge of the oesophageal mucosa with a yellow bleb on its summit. A later examination showed that the bleb had become a shallow ulcer, and a final oesophagoscopy revealed a normal mucosa. On returning home she had a similar attack associated with a herpetic eruption, a diagnosis of herpes of the oesophagus was made. These four lesions must be closely allied, since a differential diagnosis between them may be impossible. The author claims, however, that their differential diagnosis from other oesophageal conditions is simple with endoscopy, and emphasizes the importance of oesophagoscopy in all cases exhibiting oesophageal symptoms.

214. The Employment of Percaine in Oto-rhino-laryngology

O. BOSERUP (*Ugeskrift for Laeger*, April 24th, 1930, p. 411) reports from the Oto rhino-laryngological Department of the Finsen Institute in Denmark investigations made for over half a year with percaine (Ciba). For surface anaesthesia a 2 per cent. solution was used; for infiltration anaesthesia a 0·2 per cent., and later a 0·1 per cent. solution was employed, the action of the last named solution proving satisfactory. At first a 0.1 per cent. solution of adrenaline was added (nine drops to 50 c.cm. of the solution), but it was soon dispensed with in order that the action of the percaine might be the better studied. Dispensing with the adrenaline entailed more bleeding, but no demonstrable reduction of the anaesthetic action of the percaine. It was tried altogether on 93 occasions, on 15 of which it was used for surface anaesthesia during examinations of the larynx, for excisions, for galvano cauterization, and for the application of radium. On 44 occasions it was employed for surface anaesthesia for turbinectomies and the removal of polypi, and in 12 cases for infiltration anaesthesia for tonsillectomy. The patients' ages ranged from 14 to 61, and the amount of the 0·1 per cent. solution used was—in a case of laryngo fissure, for example, —between 30 and 35 c.cm. About 25 c.cm. was required for an antrum resection, 20 c.cm. for a tonsillectomy in an adult, and 10 to 15 c.cm. for the same operation in children. In no case were any signs of poisoning observed, the healing of the operation wounds ran a normal course, and there was no evidence of injury to the tissues. Anaesthesia was rapidly induced, it was complete and remarkably persistent, so much so that post operative pain was in most cases not felt. Paraesthesias and hypaesthesias seemed to be less marked than after novocain adrenaline anaesthesia. The facts that percaine can be boiled repeatedly without losing its potency and that it is cheaper than the local anaesthetics hitherto employed have enhanced its value, and the author states that his department intends to replace cocaine and novocain wholly by percaine.

Obstetrics and Gynaecology.

215. Obstetrical Anaesthesia in Private Practice.

M. HENKEL (*Med. Welt*, May 24th, 1930, p. 733) finds morphine very valuable in midwifery practice when given at the right time and in correct dosage. Scopolamine-morphine anaesthesia, as introduced by Schneiderlin, has, he thinks, many disadvantages, particularly the uncertainty of action, possible foetal asphyxia, and severe haemorrhage, but on the whole he considers it less dangerous than the newer methods. Goldschmidt and Putz have each published a series of cases treated with pernocton, just under 200 in all, they had two cases of post partum eclampsia, many patients became seriously excited, so that some had to be held down forcibly; in some instances the pains became weak, necessitating the use of pituitary extract and forceps. With avertin similar results are reported; it is given by the rectum, rendering the effect very variable, as absorption rates differ so widely in different cases. Pitlan's new method consists of injecting a

A complete infant food

It has recently been shown that the iron content of cow's milk is considerably below that of human milk, and may be inadequate to the requirements of the human infant.

In Sunshine Glaxo, the fully humanised milk-food, the need of the human infant for a complete diet with the mineral and vitamin factors scientifically adjusted, is fully met by

(a) Adding to the milk the optimum amount of "Ostelin" vitamin D.

(b) By such adjustment of the iron content as renders the product comparable, in this respect, with human milk.

Its purity, its fine, easily-digested curd and its humanised formula make Sunshine Glaxo the food of choice, when breast feeding is either impossible or needs to be supplemented.

SUNSHINE GLAXO

A free trial tin will be willingly sent on receipt of a postcard.

GLAXO LABORATORIES, 56, OSNABURGH STREET, LONDON, N.W.1.

MODERN PRACTICE in CALCIUM THERAPY

Modern research has shown that calcium and vitamin D in the body cannot be thought of in separate terms. In the absence of vitamin D calcium is not utilised by the body. Vitamin D has therefore assumed a foremost position in therapeutics.

OSTELIN (Liquid) provides a convenient form in which vitamin D may be included in all calcium prescriptions, since it is miscible with other medicaments. The usual dose is 3-10 minims.

OSTELIN TABLETS are a combination of Ostelin (Liq.) m.3. with calcium glycerophosphate gr. 2. These sugar-coated tablets are particularly indicated for adult use.

COLLOIDAL CALCIUM with OSTELIN VITAMIN D.
(1 cc. ampoules for subcutaneous injection).
Each ampoule contains 0.5. mgm of calcium in the colloidal state, together with Ostelin vitamin D to facilitate and ensure absorption.

A free trial supply of these preparations is always available on application to :—

GLAXO LABORATORIES, 56, OSNABURGH STREET, LONDON, N.W.1.

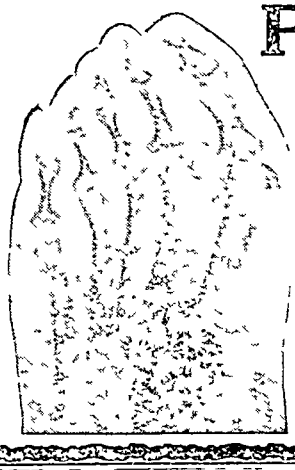
PERMANENT ALL SICKNESS AND ACCIDENT INSURANCE FOR MEDICAL MEN AT THE LOWEST RATES

The following specimen rates show the cost of each guinea per week payable during total incapacity arising from any form of Sickness or Accident, except those due to the wilful misconduct of the insured.

The full sum insured is payable for the first 26 weeks, and thereafter half that amount so long as the total incapacity lasts, up to the age of 65.

Age 25, £1 : 12 : 8 — Age 35, £2 : 1 : 0
„ 30, £1 : 16 : 5 — „ 40, £2 : 6 : 7

A Reversionary Bonus of 15/- per guinea per annum was declared on these Policies at the last valuation.



SICKNESS FUND exceeds £370,000

"ARDENTE" STETHOSCOPE.
Mr. H. Dent's Ardente Stethoscope specially for members of the medical profession suffering from deafness. Many are in use and excellent results are reported on the latest as evidenced by the interest shown at the last B.M.A. Meeting.

Doctors prefer "ARDENTE" because—

1. It is individually fitted to suit the case for young, middle aged or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises, giving inconspicuous hearing.
4. It conveys sounds from varying ranges and angles.
5. It is entirely different, unequalled and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf through various causes.
7. It is helpful for conversation, music, talkies, wireless, home, office, public work, and sports.

JOHN BELL & CROYDEN
50-52, WIGMORE STREET, W.1

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President. THE MOST HON THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders (persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes) are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses (male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches) can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical Bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres at Llanfairfechan, amidst the finest scenery in North Wales. On the North West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout fishing in the Park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56 Northampton), who can be seen in London by appointment.

COURT HALL, KENTON, EXETER,
SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone Starcross 19.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall for early and convalescent cases. Cliffden is a large well appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULLES, M.D., B.S., ANNIE S. MULLES, M.R.C.S., L.R.C.P. *Telephone*: Teignmouth 289.

BELVOIR NURSING HOME,

MEDICAL CORRESPONDENCE COLLEGE

19, WELBECK ST., LONDON, W.1. Tel. Welbeck 8901.

PROVIDES HIGHLY SUCCESSFUL ORAL AND POSTAL COACHING FOR ALL MEDICAL EXAMINATIONS.

Special Preparations for all Surgical Qualifications.

F.R.C.S.ENGLAND. (Primary & Final.) M.C.CANTAB. M.S.LONDON.

F.R.C.S.EDINBURGH.

And all other Surgical Degrees and Diplomas.

¶ The remarkable success of Students of the Medical Correspondence College at the higher Surgical Examinations is specially noteworthy.

¶ Both at the Primary and Final F.R.C.S. England the majority of our Students are successful at the first attempt, and Candidates who have failed at these Examinations on several previous occasions get through without difficulty after going through our courses.

¶ The Surgical Tutors of the College all hold either the M.S Lond. or F.R.C.S England, or both, and are highly experienced teachers.

¶ The Postal Courses are thoroughly clear, concise, and up to date, and the test questions are carefully selected from those set at previous Examinations, so as to embrace all parts of the subject. By working systematically through the Course the Student is brought up to the examination standard in the minimum time, and much unnecessary reading is saved.

VALUABLE BOOK

"How to Pass the F.R.C.S.," free on application to the Secretary.

August 2nd, 1930.

Government of Northern Ireland

APPOINTMENT OF MEDICAL OFFICER.

Applications are invited for the post of Medical Officer under the Ministry of Labour, whose duties will mainly lie in connection with the new scheme of Medical Benefit.

Candidates must have had at least 10 and preferably 15 years recent experience in general medical practice.

The salary attaching to the post will be £800—£30—£1,000, plus cost of living bonus at the Civil Service rate in force from time to time. The inclusive commencing salary at the rate of bonus payable during the six months commencing on September 1st will be £981.

Further particulars and forms of application may be obtained from the Secretary, Civil Service Commission, 15, Donegall Square West, Belfast. Applications on the prescribed forms must be received by the Civil Service Commission not later than September 20th.

County Council of Middlesex.

HILLINGDON INSTITUTION, UXBRIDGE, MIDDLESEX.

RESIDENT MEDICAL OFFICER.

The County Council invite applications for the post of Medical Officer (male) of the Hillingdon Institution at a salary of £900 per annum (no extras) with board, lodging and laundry valued at £150 per annum. The Institution is under the administrative control of the Master and provides accommodation for 400 sick and bed-ridden persons. Owing to the absence of suitable accommodation within the Institution the officer appointed will in the first place be required to live in private apartments in the neighbourhood and during this period a special allowance in respect of board and lodging will be made. On the erection of a residence within the Institution grounds the terms of the appointment in connection with emoluments will be reconsidered.

Candidates must be registered Medical Practitioners and must have held resident hospital appointments. Special experience in surgery will be an additional qualification.

The officer appointed will be required to devote his whole time to the duties of the post and to contribute to the County Councils Superannuation Fund. For the latter purpose he will be required to pass such medical examination as the County Council may direct.

The appointment is terminable by three months' notice on either side.

Applications, stating (1) name, (2) age, (3) qualifications and experience, accompanied by copies of not more than three recent testimonials, must be received by the undersigned not later than September 13th.

Canvassing is prohibited.

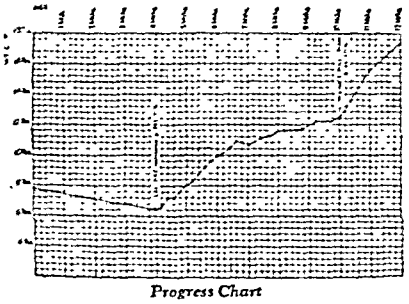
IN VITAMIN "D"

A "RESURRECTION"

.....GUILDFORD
30 6'30



"Baby Hook, came under my care shortly after birth suffering with marasmus following whooping cough. Broncho-pneumonia developed and was with great difficulty cleared up, leaving the child in a very low condition. Feeding proved a difficult problem, several things were tried without beneficial results. The results with Cow & Gate were truly wonderful, indeed it is a case of 'a resurrection.'"

(Signed).....M.B.Ch.B.

Lacidac (separated) and Brestol, the Cow & Gate Humanised Cream, were used in the early days of treatment. Cow & Gate Full Cream and Brestol being used subsequently.

BEFORE—4 months' old, 6 lbs. 9 ozs. in weight.

Progress Chart

AFTER—10 months' old, 12 lbs. 6 ozs. in weight.

June 1930. Baby Hook has now won a prize in a Baby Competition!

Write for literature and clinical samples of Lacidac and Brestol.

GWATHMEY'S ANAESTHESIA
By JAMES T. GWATHMEY, President Am. Assoc. of Anaesthetists. Second Edition. 273 Illustrations. 25s. Postage 9d.

HEWLETT'S MANUAL OF BACTERIOLOGY
Eighth Edition. 38 Plates, 63 Text-figures. 18s. Post. 9d.

CRAIG'S PSYCHOLOGICAL MEDICINE
Fourth Edition, with the Collaboration of T. BEATON, O.B.E., M.D., Lecturer in Mental Diseases, Bethlem Royal Hospital. 25 Plates. 21s. Postage 9d.

THE HAIR: ITS CARE, DISEASES AND TREATMENT

By W. J. O'DONOVAN, O.B.E., M.D., M.R.C.P., Physician, Skin Department, London Hospital; Lecturer, London School of Dermatology.
40 Illustrations. 12s. 6d. Postage 6d.

The Recent Advances Series

12s. 6d. each, except Children, Chemotherapy, and Surgery, 15s. each.

CHEMOTHERAPY
G. M. FINDLAY, C.B.E., M.D. 4 Plates, 11 Text figures.

PULMONARY TUBERCULOSIS
L. S. T. BURRELL, M.D. 32 Plates and 17 Text-figures.

PSYCHIATRY
H. DEVINE, O.B.E., M.D. Illustrated.

BACTERIOLOGY
J. HENRY DIBLE, M.B., Ch.B. 22 Illustrations.

MEDICINE
G. E. BEAUMONT, D.M., F.R.C.P., and E. C. DODDS, M.D., M.R.C.P. Fifth Edition. 49 Illustrations.

OPHTHALMOLOGY
W. STEWART DUKE-ELDER, D.Sc., M.D., F.R.C.S. Second Edition. 4 Col. Plates and 110 Text-figures.

ANALYTICAL CHEMISTRY
By C. A. MITCHELL, D.Sc., M.A., F.I.C. Vol. I, Organic. 6 Plates, 17 Text-figs.

DISEASES OF CHILDREN
W. J. PEARSON, D.S.O., D.M., F.R.C.P., and W. G. WYLLIE, M.D., M.R.C.P. Second Ed. 18 Plates and 32 Text-figs.

BIOCHEMISTRY
JOHN PRYDE, B.Sc., M.Sc. Second Edition. 38 Illustrations.

PREVENTIVE MEDICINE
J. F. C. HASLAM, *M.C.*, M.D. 30 Illus.

PLANT PHYSIOLOGY
By E. BARTON-WRIGHT, M.Sc. 51 Illus.

HAEMATOLOGY
A. PINEY, M.D. Second Edition. 4 Coloured Plates and 18 Text-figures.

CARDIOLOGY
C. F. T. EAST, M.D., F.R.C.P., and C. W. C. BAIN, *M.C.*, M.B. 12 Plates. 57 Figures.

NEUROLOGY
W. RUSSELL BRAIN, M.D., and E. B. STRAUSS, B.M., B.Ch. Second Edition. 39 Illus.

SURGERY
W. HENEAGE OGILVIE, M.D., F.R.C.S. Second Edition. 115 Illustrations.

ANATOMY
H. WOOLLARD, M.D. 4 Coloured Plates. 73 Text figures

TROPICAL MEDICINE
Sir LEONARD ROGERS, M.D., F.R.S. Second Edition. 16 Illustrations.

OBSTETRICS AND GYNAECOLOGY
ALECK W. BOURNE, M.B., B.Ch., F.R.C.S. Second Edition. 67 Illus.

PHYSIOLOGY
C. LOVATT EVANS, D.Sc., F.R.S. Fourth Edition. 113 Illustrations

London: J. & A. CHURCHILL, 40, Gloucester Place, Portman Square, W.1.

SAUNDERS' BOOKS for STUDENTS

Cecil's
Text-book of Medicine

Edited by RUSSELL L. CECIL, A.B., M.D., Assistant Professor of Clinical Medicine, Cornell University. Octavo of 1,500 pages. Cloth, 40s. net.

"This book maintains a very high level throughout its pages . . . Great care has been taken with the dovetailing together of the various central items into a compact whole, and the book is a worthy product of the modern American school of medicine."
—LANCET.

Ford's
Text-book of Bacteriology

By WILLIAM W. FORD, M.D., Professor of Bacteriology, School of Hygiene and Public Health, Johns Hopkins University. Octavo of 1,069 pages, illustrated. Cloth, 37s. 6d. net.

"This is one of the most complete single volume works on bacteriology. It is more than a text book, as it is described, and constitutes a valuable work of reference with a wealth of detail particularly in systematic bacteriology . . . The book can be strongly recommended."—EDINBURGH MEDICAL JOURNAL.

Morse's
Applied Biochemistry

By WITHROW MORSE, Professor of Physiological Chemistry, Jefferson Medical College, Philadelphia. Octavo of 988 pages, illustrated. Second (Revised) Edition. Cloth, 32s. 6d. net.

"The author has succeeded in conveying to the reader the idea that biochemistry is an active dynamic subject. . . Professor Morse has rendered a wonderful service to biochemistry and its students."—LANCET.

Howell's
Text-book of Physiology

By WILLIAM H. HOWELL, M.D., Ph.D., Professor of Physiology, Johns Hopkins University, Baltimore. Octavo of 1,081 pages. Illustrated. Cloth, 30s. net.

"One of the best, most readable, suggestive, and withal critical of the modern text-books on this subject. Is sound, accurate, physiological, and thoroughly up to date."—LANCET.

Garrison's
History of Medicine

By FIELDING H. GARRISON, M.D., Lieutenant-Colonel Medical Corps, U.S. Army, Surgeon-General's Office, Washington, D.C. Octavo of 996 pages, with numerous portraits and other pictures. Fourth Edition. Cloth, 55s. net.

"The most readable, and in many respects the most valuable of medical histories. The record of progress is enlivened throughout by touches of human interest. The author is never dull . . . We congratulate Dr. Garrison on having produced a fascinating volume, which, while full of solid learning, can, unlike most histories of medicine, be read from end to end without a yawn."—BRIT. MED. JOURN.

Dorland's
Illustrated Medical Dictionary

Edited by W. A. NEWMAN DORLAND, M.D. Octavo of 1,427 pages, 525 illustrations, 107 in colours. New (15th) Ed. Flexible binding. 35s. net.

"In this, its latest form, 'Dorland' will retain its old friends and find many new friends."—LANCET.

Sollmann's
Manual of Pharmacology

By TORALD SOLLMANN, M.D., Professor of Pharmacology, Western Reserve University. Octavo of 1,184 pages. Third (Revised) Edition. Cloth, 35s. net.

"It is a mine of information from which both student and practitioner may draw with benefit, and with confidence."—LANCET.

Wechsler's
Clinical Neurology

By ISRAEL S. WECHSLER, M.D., Assistant Professor of Clinical Neurology, Columbia University. Octavo of 725 pages, illustrated. Cloth, 32s. 6d. net.

"It serves its purpose well, and for the student and practitioner it appears to constitute a useful compendium of practical neurological medicine."—LANCET.

McGuigan's
Text-book of Therapeutics

By HUGH ALISTER McGUIGAN, Ph.D., M.D., Professor of Pharmacology and Therapeutics, University of Illinois College of Medicine. Octavo of 660 pages, illustrated. Cloth, 28s. net.

"Professor McGuigan has succeeded in producing something quite different from the usual run of books on pharmacology and therapeutics suitable for under graduates. . . . One can unhesitatingly recommend the book to the attention of students of medicine in search of an accurate book of reasonable dimensions."
—SOUTH AFRICAN MEDICAL JOURNAL.

Bolduan's
Public Health and Hygiene

By CHARLES F. BOLDUAN, M.D., Director, Bureau of Health Education, Department of Health, City of New York. 12mo. of 312 pages, illustrated. Cloth, 12s. 6d. net.

"This is essentially a manual for students. It does not go into details as much as most elementary works on Public Health and Hygiene, but it presents the subject in an unconventional and most interesting way. The book is copiously supplied with excellent illustrations and diagrams."
—BRITISH JOURNAL OF MEDICAL SCIENCE.

Todd & Sanford's
Clinical Diagnosis

By JAMES CAMPBELL TODD, M.D., University of Colorado, and ARTHUR HAWLEY SANFORD, M.D., University of Minnesota (The Mayo Foundation). Octavo of 782 pages with 348 illustrations, 29 in colours. Sixth, Revised, Edition. Cloth, 28s. net.

"A book which is of particular value to the student, for the number and the excellence of the illustrations, the clarity of the language and the short, but concise, notes on the indications for the applications of various tests and the interpretation of the results."—LANCET.

Ranson's
Anatomy of Nervous System

By STEPHEN W. RANSON, M.D., Professor of Neurology, Northwestern University Medical School, Chicago. Octavo of 425 pages, with 281 illustrations, some in colours. Third, Revised, Edition. Cloth, 32s. 6d. net.

"Can be confidently recommended to the students of gross anatomy as a book which will lighten the dark tracts of the nervous system."—BRITISH JOURNAL OF MEDICAL SCIENCE.

Griffith & Mitchell's
Diseases of Children

By J. P. CROZER GRIFFITH, M.D., Professor of Pediatrics, University of Pennsylvania, and A. GRAEME MITCHELL, M.D., Professor of Pediatrics, University of Cincinnati. Two octavo volumes totalling 1,500 pages, illustrated. Second Edition thoroughly revised. Cloth, 90s. net.

"This book should be of the greatest assistance to post graduate students, to whom its value will be greatly increased by the comprehensive and well chosen list of references to original papers."
—LANCET.

W. B. SAUNDERS COMPANY Ltd., 9, Henrietta Street, LONDON, W.C.2

LEWIS'S PUBLICATIONS

RECENTLY PUBLISHED. SECOND Ed. With 74 Illus. on 31 Plates and in the Text. Demy 8vo. 16s. net; post. 9d.

A SHORTER SURGERY

A Practical Manual for Senior Students

By R. J. McNEILL LOVE, M.B., M.S.Lond., F.R.C.S.Eng., Assistant Surgeon, Metropolitan Hospital, Hunterian Professor, Royal College of Surgeons, etc.

"It is an achievement to have compressed in such a small compass a readable account of modern surgery."—THE LANCET.

With 130 Illustrations. Demy 8vo. 18s. net; postage 9d.

A SHORTER ANATOMY: With Practical Applications

By E. WOLFF, M.B., B.S.Lond., F.R.C.S.Eng., Demonstrator of Anatomy, University College, London, Lecturer in Surgical Anatomy, University College Hospital Medical School, Author of "Anatomy for Artists," etc.

"... eminently practical and should be of considerable value to the senior student and to the practitioner. The illustrations are excellent and show just what is required."—THE PRACTITIONER.

With 176 Illustrations on 52 Plates. Crown 4to. 7s. 6d. net, postage 6d.

ELEMENTARY PATHOLOGICAL HISTOLOGY

By W. G. BARNARD, M.R.C.S., Pathologist, University College Hospital, formerly Junior Assistant Director of the Institute of Pathology at the London Hospital.

"Dr. Barnard is to be congratulated on a book which will certainly be deservedly popular with students. It is beautifully produced and inexpensive."—THE LANCET.

With Illustrations. Demy 8vo. 12s. 6d. net, postage 9d.

ELEMENTARY MEDICINE IN TERMS OF PHYSIOLOGY

An Introduction to Clinical Work.

By D. W. CARMALT JONES, M.A., M.D.Oxon., F.R.C.P.Lond., Professor of Systematic Medicine, University of Otago, New Zealand; Physician, Dunedin Hospital, New Zealand; Consulting Physician, Westminster Hospital, etc.

"... will be widely used—an excellent introduction to clinical medicine."—BRISTOL MEDICO CHIRURGICAL JOURNAL.

SEVENTH Edition. With new Illustrations (mostly in Colour). Demy 8vo. 7s. 6d. net, postage 6d.

LANDMARKS AND SURFACE MARKINGS OF THE HUMAN BODY

By L. BATHE RAWLING, M.B., B.C.Cantab., F.R.C.S.Eng., Surgeon to St. Bartholomew's Hospital, etc.

"This edition will doubtless be as popular as its predecessors, both with students and surgeons."—BRITISH MEDICAL JOURNAL.

SECOND Edition. With new Illustrations. Oblong Imp. 4to. 21s. net, postage 9d.

With an Atlas of the Normal.

By W. IRONSIDE BRUCE, M.D.

Revised by J. MAGNUS REDDING, F.R.C.S., Senior Surgical Radiographer, Guy's Hospital, etc.

"... alterations and additions have been made which greatly increase the value of the work. The illustrations ... form an additional collection of skiagrams finely reproduced."—BRITISH JOURNAL OF RADIOLOGY.

EIGHTH Edition. With 2 Plates and 91 other Illustrations. Demy 8vo. 21s. net; postage 9d.

HYGIENE AND PUBLIC HEALTH

(PARKES AND KENWOOD)

Revised by HENRY R. KENWOOD, C.M.G., M.B., F.R.S.Edin., D.P.H.Lond., Emeritus Professor of Hygiene and Public Health in the University of London, etc.; and HAROLD KERR, O.B.E., M.A.Dunelm, M.D.Edin., D.P.H. Camb., Professor of Hygiene and Public Health in the University of Durham, etc.

"Here we have a quarry of concise information valuable to students and practical workers, a bargain at the price asked for it."—BRITISH MEDICAL JOURNAL.

RECENTLY PUBLISHED. With Illustrations. Demy 8vo. 28s. net; postage 1s.

HUMAN BIOLOGY AND RACIAL WELFARE

Edited by E. V. COWDRY, Ph.D., Prof. of Cytology, Washington Univ., St. Louis. Introd. by EDWIN R. EMBREE.

Publisher's Note.—"This volume aims to present the current status of scientific knowledge in those branches of science most vitally affecting man, and grouped for convenience under the heading of 'Human Biology.' Each authority covers his special field conservatively and plainly, with adherence to fact and with racial welfare in mind."

RECENTLY PUBLISHED. With 111 Illustrations. Demy 8vo. 15s. net, postage 9d.

A Text-Book on the

NURSING AND DISEASES OF SICK CHILDREN

for Nurses and Welfare Workers.

By Various Authors. Edited by ALAN MONCRIEFF, M.D., B.S., M.R.C.P. Lond., Medical Registrar and Pathologist to the Hospital for Sick Children, Great Ormond Street.

CONTRIBUTORS.—T. TWISTINGTON HIGGINS, O.B.E., F.R.C.S.; ERIC I. LLOYD, F.R.C.S.; BERNARD SCHLESINGER, M.B., B.Ch., M.R.C.P. With the collaboration of M. A. RUSSELL, S.R.N.

"It is clear, detailed, and accurate, and is illustrated where necessary by some useful diagrams and photographs."—BRITISH MEDICAL JOURNAL.

THIRD Edition. Fcap. 8vo. 10s. net, postage 4d.

THE LONDON HOSPITAL LECTURES ON FORENSIC MEDICINE AND TOXICOLOGY

By the late F. J. SMITH, M.A., M.D.Oxon., F.R.C.P.Lond., F.R.C.S.Eng. Revised by G. JONES, M.B.Oxon., M.R.C.S., D.P.H.

"Students should be grateful to the Editor, who, in bringing the book up to date, has preserved its value for another generation."—ST. BARTHOLOMEW'S HOSPITAL JOURNAL.

RECENTLY PUBLISHED. THIRD Edition. With additional Chapters. Demy 8vo. 9s. net; postage 6d.

THEORY AND PRACTICE OF NURSING

By M. A. GULLAN, Sister Tutor at St. Thomas's Hospital.

The Student's Handbook of Gynæcology

By G. ERNEST HERMAN, M.B., F.R.C.P. Lond., F.R.C.S.Eng. *Second Edition* With additions by R. DRUMMOND MAXWELL, M.D.Lond., F.R.C.S.Eng Illus. 10s. net.

CASSELL & CO., LTD., LA BELLE SAUVAGE, LONDON, E.C.4

JOHN BALE, SONS & DANIELSSON, LTD.

GENERAL PRACTICE (Some Further Experiences). By ERNEST WARD, M.D., F.R.C.S., author of "Medical Adventure," etc. **3s. 6d.** net; post free 4s.

"There is not a chapter in this book where the young practitioner will not find some guiding word—some apt piece of counsel for application in the conduct of practice."—LANCET.

"The book is extremely interesting and concise . . . we strongly recommend it to all senior medical students."

—MANCHESTER UNIVERSITY MEDICAL SCHOOL GAZETTE.

MEDICAL ADVENTURE. Some Experiences of a General Practitioner. By ERNEST WARD, M.D., F.R.C.S. **8s. 6d.** net; post free 9s.

"A remarkable book. It is a record, freely annotated, of a man with a rich experience of many sides of a doctor's life . . . should prove most useful as well as entertaining."—LANCET.

"THE CONJOINT FINALS" Being a Reproduction of all the Questions set in Medicine, Surgery, and Midwifery from 1911 to 1929 classified under the various systems and arranged in the date-order of their occurrence. By GERALD H. BEESTON, M.R.C.S.(Eng.), L.R.C.P. (Lond.). 6s. net; post free inland 6s. 6d.; abroad 6s. 9d.

"The book is intended to provide a sound scheme for general revision, and all students approaching that great crisis in their careers, the Finals, would do well to get hold of a copy."

—CHARING CROSS HOSPITAL GAZETTE.

THE CLINICAL PATHOLOGY OF THORACIC PUNCTURE FLUIDS By S. ROCKHOUSE GLOYNE, M.D., D.P.H., Pathologist, City of London Hospital for Diseases of the Heart and Lungs, Victoria Park. **10s. 6d.** net; post free 11s.

This is the only book devoted entirely to this subject.

"The book is very well classified and the practical details exceedingly good and of real technical interest and value. The bacteriological section is complete and notably relevant. . . . It is an extremely useful and compact handbook and will be of great interest and value to both the clinician and laboratory workers."

—MIDDLESEX HOSPITAL JOURNAL.

HANDBOOK ON TUBERCULOSIS. By B. S. KANGA, M.D., D.P.H., Medical Officer, Turner Dispensary, and Visiting Medical Officer, Turner Sanatorium (Bombay Municipality). **5s.** net; post free 5s. 6d.

"This book, possessing the merits of being very readable and non-dogmatic, may prove useful to those who have not time to study the larger standard works."

—JOURNAL OF THE MEDICAL ASSOC. OF S. AFRICA.

SEX AND ITS MYSTERIES. By GEORGE RYLEY SCOTT, **10s. 6d.** net; post free 11s.

"A book of considerable merit. . . . Covers the ground of a somewhat difficult subject very completely, and its publication will do much to clear away many misunderstandings which have crept into our social life on sexual matters owing to lack of a proper knowledge concerning them."—MEDICAL WORLD.

THE PRINCIPLES OF ANTE-NATAL AND POST-NATAL CHILD HYGIENE. By W. M. FELDMAN, M.D., B.S., M.R.C.P.Lond., F.R.S.Ed.n. With 161 Illustrations and 14 Plates, including over 100 Portraits. **25s.** net: post free 25s. 9d.

"The author has attempted, and has succeeded in, the difficult task of producing a book which will interest alike paediatric physicians, lay workers at infant welfare centres, students of ante-natal care and welfare, and all concerned with the well-being of children. The general practitioner will find in it answers to the innumerable questions of young parents. . . . These and other subjects are dealt with concisely but in detail, the attractive style of the writing preventing the weariness in reading that would otherwise be inevitable."—BRITISH MEDICAL JOURNAL.

A GRAPHIC GUIDE TO ELEMENTARY SURGERY. By PROF. DR. TH. NAEGELI, Bonn. Translated by J. SNOWMAN, M.D., M.R.C.P. With Introduction by Dr. C. GARRÉ, Bonn. 322 Illustrations (mostly Coloured). **12s. 6d.** net; post free 13s.

"The idea of producing a graphic clinical surgical manual is commendable, and particularly it will appeal to the junior student. Dr. Naegeli's book will convey to the reader a large amount of surgery in small compass, and easily assimilable form."—MED. PRESS.

OUTLINES OF SCIENTIFIC ANATOMY. By DR. WILHELM LUBOSCH, Prof. of Anatomy in Würzburg. **For Students of Biology and Medicine. Designed to supplement the usual Textbook Teaching.** Translated by DR. H. H. WOOLLARD, M.D., formerly Assistant Professor of Anatomy, University College, London. 66 Illustrations. **21s.** net; post free inland 21s.6d.; abroad 22s.6d.

"An excellent translation of an extremely valuable book, in which Professor Lubosch discusses, in a most illuminating manner, the outlines of the science of anatomy."—EDINBURGH MEDICAL JOURNAL.

THE MORPHOLOGY AND EVOLUTION OF THE APES AND MAN. By CHARLES F. SONNTAG, M.D., Ch.B., F.Z.S., late Prosector to the Zoological Society of London, and Demonstrator of Anatomy, University College, London. Foreword by Prof. G. ELLIOT SMITH, M.D., F.R.S. With 59 Illustrations. **12s. 6d.** net; post free 13s.3d.

"The book is likely to be a work of reference on its subject for many years to come, and we recommend all who are interested in this matter to procure it."—LANCET.

ATLAS OF SYPHILIS. By PROF. LEO. V. ZUMBUSCH. With 63 Illustrations taken direct from nature by Colour Photography, and one single-colour Illustration. **30s** net; post free 30s. 9d.

"Reproduces the appearance of cutaneous syphilis better than any others we have previously seen."—BRITISH MEDICAL JOURNAL.

A NEW EDITION OF

CLINICAL SURGICAL DIAGNOSIS. For Students and Practitioners. By F. DE QUERVAIN, Professor of Surgery and Director of the Surgical Clinic at the University of Basle. Translated from the 9th Edition by J. SNOWMAN M.D., M.R.C.P. 4th English Edition, with 750 Illus. and 7 Col. Plates. **42s.** net; post free 43s. 3d.

". . . can be confidently recommended to students and practitioners, for it is unrivalled. No book on surgical diagnosis equals it in fullness, accuracy, and insight."—BRIT. JOUR. OF SURGERY.

THE IMMUNOLOGY OF PARASITIC INFECTIONS. By WILLIAM H. TALIAFERRO, Ph.D., Professor of Parasitology, University of Chicago. Illustrated. **25s.** net; post free inland 25s. 9d. net; abroad 26s. 6d.

"An important contribution to medical literature and one which should focus the attention of tropical workers in particular on the deficiencies and gaps in present knowledge of this important subject."—LANCET.

INDISPENSABLE TO EVERY MISSIONARY.

A book giving invaluable information to a Missionary when away from medical aid. Over 600 pages of helpful matter for preserving the health and dealing with sickness in the Tropics, for the small cost of **12s. 6d.** net, post free inland 13s. 3d., abroad 14s.

A MANUAL OF TROPICAL DISEASE AND HYGIENE FOR MISSIONARIES. 2nd Ed. Revised. Edited by EDWIN A. NEATBY, M.D., and T. MILLER NEATBY, M.A., M.D. With Forewords by Sir ALDO CASTELLANI, K.C.M.G., M.D., F.R.C.P., and Sir JAMES CANTLIE, K.B.E. Illustrated by 20 Plates (14 coloured) and 118 Figures and Charts.

LABORATORY STUDIES IN TROPICAL MEDICINE. By C. W. DANIELS, M.B.Cantab., F.R.C.P.Lond., and H. B. G. NEWHAM, C.M.G., M.D., M.R.C.P.Lond., D.P.H. 5th Ed. Thoroughly revised, with many new and additional Illustrations. **25s.** net; post free 26s.

"A thoroughly practical guide to the student of tropical medicine, and is sure to maintain the popularity previous editions have enjoyed."—BRITISH MEDICAL JOURNAL.

A TREATISE ON KALA-AZAR. By UPENDRANATH BRAHMACHARI, K.-I.-H. (Gold), Rai Bahadur, M.A., M.D., Ph.D. 13 Plates (7 Coloured). *21s. net; post free inland 21s. 9d., abroad 22s. 10d.*

A new book embodying all the latest facts known about the probable transmission of the disease and the latest advances in its treatment.

"The first impression which one obtains on glancing through this sumptuous book is the extremely high standard of publication reached. . . . We must warmly congratulate Dr. Brahmarchari on the publication of this volume."—INDIAN MEDICAL GAZETTE.

"Undoubtedly a most comprehensive and exhaustive treatise on kala-azar . . . up-to-date and much sought after information is to be found in Dr. Brahmachari's admirable book."

—JOURNAL OF TROPICAL MEDICINE AND HYGIENE.

TROPICAL SURGERY AND SURGICAL PATHOLOGY. By KURUNA K. CHATTERJI, F.R.C.S.I., Major I.T.F. Medical Corps. With a Foreword by Major-General Sir R. HAVELOCK CHARLES, G.C.V.O., K.C.S.I., M.D., F.R.C.S.I. With 135 Plates, 17 in Colour, and 5 Charts. **16s.** net: post free 17s. 6d.

"It is a pleasure to welcome such a book as 'Tropical Surgery and Surgical Pathology,' for it is certainly needed. . . . In the Introduction Major Chatterji mentions that he is handicapped by writing in a foreign language; we could wish that this same language held no greater handicap for many of those who learnt it at their mother's knee, for the clarity of the exposition alone makes the book worth reading. Definite and minute instructions are given for various operative procedures as well as general measures. . . . The volume includes a foreword by Sir Havelock Charles and a useful bibliography; it is profusely illustrated, and numerous coloured plates are given. Indeed, the author and publishers are to be congratulated upon the production of such a well turned out book at a reasonable price."—BRITISH MEDICAL JOURNAL.

THE AMŒBÆ LIVING IN MAN. By CLIFFORD DOBELL, M.A., F.R.S. With 5 Plates (2 Coloured). **7s. 6d** net; post free 8s. 3d.

"As a text-book for the student we can think of no better work than this . . . should remain a standard work on the subject for some time."—LANCET.

THE INTESTINAL PROTOZOA OF MAN. By CLIFFORD DOBELL, M.A., F.R.S., and F. W. O'CONNOR, M.R.C.S., L.R.C.P., D.T.M. & H. Published for the Medical Research Council. With 8 Plates (3 Coloured). **15s.** net.; post free 16s.

"The book should be read by every student of this highly specialized subject. It is the only up-to-date account of the human intestinal protozoa which exists, and the authors are to be congratulated on having presented to the scientific world such an excellent treatise."—LANCET.

MANUAL OF EMERGENCIES. Medical, Surgical, and Obstetric. Their Pathology, Diagnosis, and Treatment. By J. SNOWMAN, M.D., M.R.C.P. **10s.** net; post free 10s. 6d. **2nd Ed**

"We are convinced that no general practitioner who has seen this work would willingly be without it."—POST-GRADUATE MED. JOURN.

ON WRITING THESES FOR M.B. & M.D. DEGREES. By SIR HUMPHRY D. ROLLESTON, K.C.B., M.D. P.R.C.P. **1s.** net; post free 1s. 3d. Second Revised Edition.

"One of the best of medico-literary first-aid manuals . . . should prove of great value to those who have to write theses, and we might add that many others would derive profit from reading it."—BRITISH MED. JOURN.

SURGICAL TREATMENT OF PULMONARY AND PLEURAL TUBERCULOSIS. By J. GRAVESEN, M.D.(Copenhagen), Med. Superint., Vejlefjord Sanatorium, Denmark. With a Foreword by S. VERE PEARSON, M.D., M.R.C.P., Res. Physician, Mundesley San. 87 Illus. (3 in col.). **10s. 6d.** net: post free 11s. 3d.

"Dr. Gravesen's book fills a gap . . . will remain a standard work on this subject for years to come."—LANCET.

LIPPINCOTT BOOKS

OPERATIVE SURGERY: GENERAL AND SPECIAL CONSIDERATIONS

By Dr. MARTIN KIRSCHNER, Professor of Surgery and Director of the Surgical Clinic at the University of Tubingen, Germany. Authorised translation by I. S. RAVDIN, B.S., M.D.
With 746 Illustrations, MOSTLY COLOURED. READY AUTUMN. 50s.

The presentation of the first English edition of Kirschner's work is offered without apologies. A work so skilfully and beautifully illustrated fills a definite need in surgical literature. It is a book that will not only appeal to the surgeon, but also to the practitioner, who must do some of the minor surgery, which is shown in this beautiful Colour Surgery.

CLINICAL NUTRITION and FEEDING in INFANCY and CHILDHOOD

By I. NEWTON KUGELMASS, M.D., Ph.D., Sc.D.
37 Illustrations. Ready Autumn 25s.

FRACTURES and DISLOCATIONS: Treatment and After Care

Second Edition Revised.
By PHILIP D. WILSON, M.D., and WILLIAM A. COCHRANE, M.D. 1,029 Illustrations. 45s.

"We can safely recommend this book as one of the best and most up to date guides for the general practitioner, as well as for the expert surgeon and the student."—BRIT. MED. JOURN.

PHYSICAL DIAGNOSIS

Second Edition Revised.
By CHARLES PHILLIPS EMERSON, A.B., M.D., author of "Clinical Diagnosis." 324 Illustrations. 35s.

"The book deserves a wide popularity amongst students and medical practitioners alike."—THE LANCET.

LIPPINCOTT'S QUICK REFERENCE BOOK for MEDICINE and SURGERY

By GEORGE E. REHBERGER, A.B., M.D. Seventh Edition. 3 Folding Manikins. 33 Coloured Plates. 151 Illustrations. 65s.

PHYSICAL & CLINICAL DIAGNOSIS

By Dr. OTTO SEIFERT and Dr. FRIEDRICH MUELLER. Authorised translation from the 24th German edition by E. COWLES ANDRUS, M.D. 140 Illustrations and 3 coloured inserts. 25s.

DISEASES OF THE EAR

By PHILIP D. KERRISON, M.D. Fourth Edition. 332 Illustrations and 2 full pages in colours. 35s.

VALUABLE BOOKS on

TROPICAL MEDICINE

BIRDWOOD:—CLINICAL METHODS FOR STUDENTS IN TROPICAL MEDICINE

A Guide for Students and General Practitioners in the Tropics in Diagnostic and Therapeutic Measures.

By G. T. BIRDWOOD, M.A., M.D., D.P.H., Lt.-Col., I.M.S., late Principal, Medical School, Agra, Surgeon, War Memorial Hospital, Deal; Contributions by Lt.-Col. W. F. HARVEY, M.B., I.M.S., Director, Research Institute, Kasauli; Maj.-General J. MEGAW, M.D., I.M.S., late Principal, School of Tropical Medicine, Calcutta; Lt.-Col. S. R. CHRISTOPHERS, M.B., C.I.E., O.B.E., I.M.S., Research Institute, Kasauli; Lt.-Col. H. W. ACTON, I.M.S., Principal, Calcutta School of Tropical Medicine; Lt.-Col. H. J. WALTON, M.D., F.R.C.S.; and Dr. H. B. NEWSHAM, C.M.G., Curator of Museum, London School of Tropical Medicine.

Fourth Edition. Foolscap. 8vo. Cloth. 14s.

This valuable reference book is a miniature encyclopedia giving the essential details of every contingency that can possibly arise in Medical practice. Although primarily issued for the tropics it can be profitably studied or used as an aide-memoire anywhere.

KNOWLES:—AN INTRODUCTION TO MEDICAL PROTOZOOLOGY

By ROBERT KNOWLES, Lt.-Col., Indian Medical Service, Professor of Protozoology, Calcutta School of Tropical Medicine. With 174 Text Illustrations and 15 full-page Coloured Plates. A bibliography of 1,800 references and a full-page index. Crown quarto £2 1s. 8d.

The Calcutta School of Tropical Medicine will always be a wonderful source of original research. Anyone interested in Protozoology should not miss reading this book.

KNOWLES AND SENIOR-WHITE:—MALARIA

Its Investigation and Control with special reference to Indian Conditions.

By ROBERT KNOWLES, Lt.-Col., Indian Medical Service, Professor of Protozoology, Calcutta School of Tropical Medicine, and RONALD SENIOR-WHITE, Malaria Research Officer, Central Malaria Bureau, Government of India, formerly Malariologist, The Kepitigalla Rubber Estates, Ltd., Ceylon; and Malariologist, Bengal-Nagpur Railway Co., Ltd. With many plates and diagrams. Crown 4to. Waterproof binding 12s. 6d.

A valuable and most interesting book containing the results of original research laboratory work, surveys, entomology, and treatment. Should be in the hands of every doctor who is at all likely to meet malaria.

New 1930 Complete Revisions

OSLER'S Principles and Practice of Medicine

Once again, 1930, Dr. McCrae has brought the incomparable Osler completely up to date. In the ELEVENTH EDITION he has introduced many new subjects and searchingly revised the entire text to conform with the advances and developments of the present time. Osler described the whole field clearly and concisely and his classic text remains unchallenged for completeness, clarity of expression, and uniformity of style. As a textbook it remains unequalled. 30/-.

WILLIAMS' Obstetrics

Nearly every page has been changed in this new, SIXTH EDITION of a work which, more than any other, is the standard in its field. Among other changes may be mentioned the consideration of the transformation of the generative tract during pregnancy, folliculine and the relationship of the anterior lobe of the hypophysis to pregnancy; the practical conduct of labour: obstetrical anaesthesia: multiple pregnancy: the induction of labour; low cervical cesarean section; the toxaemias of pregnancy and the treatment of puerperal infection.
Obstetrics is up to 1930. 40/-.

JORDAN'S Textbook of Histology

This, the FIFTH EDITION attests the continued favourable reception of the preceding editions, and the progress made during the past few years. The author has taken the opportunity to improve many illustrations, and to make many textual changes and additions, particularly in the chapters on the blood and the endocrine tissues. Altogether, the revision is thorough, and the book is right up to the minute. 25/-.

Safeguarding the Future

NOW, at the beginning of a medical career, is the time to consider what protection from everyday risks is necessary and the manner in which it shall be obtained.

Insurance, by means of first-rate policies, which can be arranged by the Medical Insurance Agency, provides a certain and inexpensive way of safeguarding against misfortunes of to-morrow.

The expense of a medical education is costly. A suitable Life or Endowment Policy will protect such cost if early death should occur.

Sickness and Accident Policies, to meet the case of entrants to the Profession, are recommended by the Agency, and full particulars will be sent on request.

Whatever your special needs, you are urged to communicate with the Agency which was founded in 1907 to assist members of the profession in all matters pertaining to Assurance and Insurance. It's advice is free and unbiassed.

What the Agency has done for the Profession.

SAVED by way of Rebates on Premiums over £39,000.

CONTRIBUTED to Medical Charities over £25,500.

When a life is at stake.....

The psychological moment has arrived. Will the operation be successful? . . . Can modern science triumph over such disease? . . . The surgeon bends closer over the table . . . deft fingers touching slender instruments . . . a life is at stake . . . if the lights should fail, plunging the theatre into darkness . . .

Nowhere is reliable light supply more important than in operating theatres. A light failure may have far reaching consequences. Every hospital should be equipped with Ediswan Stationary Battery. Then if current fails, a switch over to the Ediswan saves the situation and restores light almost immediately.

The Ediswan Stationary Battery for Emergency Lighting is compact and robust. It takes up little space and is sturdily built to give long service. Running costs are almost negligible. Installation costs are low.

May we co-operate with you in evolving a Battery specially to suit your requirements?

To Relieve Chronic Intestinal Stasis in Women

When you have a patient with chronic intestinal stasis due to diminished tonicity and stretching of abdominal muscles following a pregnancy, you will obtain excellent results from the mechanical support provided by a Spencer Belt.

Equally satisfactory results are obtained by the use of a Spencer Abdominal Belt for cases where atrophy and diminished tonicity are due to toxaemia and loss of fat following a severe illness or an abdominal operation, or in any case where enteroptosis exists.

SPENCER BELT

The back of the Spencer Belt is made long enough for comfort, and to provide adequate back support.

The front of the garment curves in snugly to the pubic bone, and is so designed and adjusted that it uplifts the abdomen instead of compressing it.

Spencer Belts to relieve chronic intestinal stasis will be provided with ptosis pads if the physician desires it.

Each Spencer Belt is designed to meet the special needs of the individual who will wear it. You can therefore prescribe and obtain exactly what your patient needs.

The Spencer Corsetiere will call at your surgery or at *your patient's home* to take measurements under your supervision.

We issue booklets on the use of Spencer Supports for the relief of enteroptosis, hernia, movable kidney, sacro-iliac strain, and for maternity wear. We will gladly send you any in which you are interested.

every nurse should know . . .

A NURSE owes it to her own professional pride and to the safety of her patient to know the facts about Lysol.

When Lysol was first discovered a formula was worked out: a specification evolved for the manufacture of a perfect antiseptic and germicide. This is the formula: this the specification used to-day in the manufacture of Marshall's Lysol.

Marshall's Lysol costs a few pence more than other brands, because every bottle sold is uniform in purity: because every precaution that science teaches is taken to maintain this high standard.

Other Lysols may contain inferior ingredients: impurities may make them caustic, irritant . . . But Marshall's Lysol used as directed is harmless to skin and tissue: death to disease. It is an essential part of every nurse's equipment. Never use Marshall's Lysol undiluted.

From qualified Chemists only. 1/-, 1/9, 3/-, & 5/-. Trial size 6d. The larger sizes are more economical to buy.

Sample sent upon request to members of the Medical and Nursing Professions.

MARSHALL'S Lysol

LYSOL Ltd., RAYNES PARK, LONDON, S.W.20

Builds up in underweight conditions and provides a perfectly balanced, highly nutritive diet for growing children

TO the problem of the "underweight" child Horlick's Malted Milk provides a convenient solution.

For many years it has been successfully used by the medical and nursing professions for fast-growing children, for invalids, for expectant and nursing mothers — in all cases where it is particularly important to sustain strength and replenish natural energy quickly.

Excellent results obtained by adding Horlick's to the diet of growing children have been strikingly recorded in many thousands of letters written by parents and members of the medical profession.

Made from fresh, full-cream cows' milk, selected wheat and malted barley, Horlick's Malted Milk constitutes a perfectly balanced food — containing fat, proteids, and soluble carbohydrates in correct nutritive ratio.

The vitamins of its constituents are unimpaired by the Horlick process.

Horlick's contains neither cane sugar nor unaltered starch, but presents in proper proportions a sufficiency of valuable malt sugars, for which children have a greater toleration. Moreover, Horlick's is partially pre-digested during manufacture, thereby assuring perfect assimilation.

In addition to its important body-building qualities, Horlick's has the advantage of being an extremely palatable beverage. Most children like the natural flavour of malt and will drink Horlick's with pleasure. And it is now obtainable also in a new Chocolate Flavoured form — identical in constituents with the original Horlick's, but with fine chocolate added.

Horlick's Malted Milk (both forms) is obtainable everywhere in sealed glass bottles, at 2/-, 3/6, 8/6 and 15/-. Also in tablets.

Further details and supplies for tests may be obtained from Horlick's Malted Milk Co., Ltd., Slough, Bucks.

Bismuth-Formic-Iodide Compound

Mulford B-F-I

Supplied in 2 sizes in sprinkler-top tins.

Bismuth-Formic-Iodide Compound, now well known as "B-F-I", is a medicated dusting powder possessing soothing, astringent and antipruritic properties. It is a safe, dry dressing that promotes healing and has been widely used for thirty years by physicians and in hospitals.

B-F-I has the capacity for absorbing fluid from the surface, thereby exerting a drying action. It does not cake or form hard crusts, which would only add to the irritation. B-F-I is, therefore, the ideal dusting powder for use wherever excoriation and a weeping surface occurs.

This compound has been found very satisfactory and effective in treating superficial wounds, eczema, impetigo, pemphigus, ulcers, burns, abscesses, vaccination area, bed or fever sores, chafing, abrasions and similar skin irritations.

A pure carbohydrate food

that combats constipation, auto-intoxication & colitis

Lactose 73%, dextrin 25%—that is the proportion in which these carbohydrates are combined in this new food for changing the intestinal flora. Both are more slowly absorbed than other carbohydrates, and both are able to reach the colon in sufficient quantity to cause a luxuriant growth of protective flora. An acid reaction of the intestinal contents unfavourable to toxic organisms is thus produced—Lacto-Dextrin being highly efficient in promoting the growth and development of both B. acidophilus and B. bifidus in the colon. In this pure carbohydrate food both lactose and dextrin are presented in a palatable and agreeable combination.

PSYLLA

. . . an accessory for use in conjunction with Lacto-Dextrin

Where bulk and lubrication of the intestinal tract is also required, the use of BATTLE CREEK Psylla (Plantago Psyllium) is invaluable as an accessory. The small brown seed when in contact with water swells into a soft gelatinous mass and acts most effectively both as an emollient and intestinal evacuant.

Samples and literature of both these intestinal products will be sent to members of the Medical Profession on request to Coates & Cooper, 41, Gt. Tower St., London, E.C.3, Sole Distributing Agents for the United Kingdom and Irish Free State.

LACTO-DEXTRIN

Manufactured by the BATTLE CREEK FOOD CO., Mich., U.S.A.

A POWERFUL SAFE GERMICIDE

THE mere statement that the R.W. coefficient of an antiseptic is 2, 20, or even 50, is of little value in estimating its usefulness for any variety of purposes. The test organism employed in this method is B. Typhosus, and an antiseptic which will kill this organism in high dilution will not necessarily kill others under similar conditions.

The coal-tar group of antiseptics has a selective action on bacilli of the typhoid-coli group, with the consequence that Rideal-Walker coefficients for these products are remarkably and deceptively high. If the same test is performed using a variety of other organisms, it will commonly be found that there are no two distinct varieties for which the coefficient is the same.

The selective action of Monsol differs from that of any other antiseptic known. Perhaps its most valuable action is on the Streptococcus Pyogenes, which Monsol destroys at dilutions 10 times greater than those at which phenol or lysol are effective.

Monsol is bland in action, and in therapeutic concentrations non-irritant even to mucous membranes.

MONSOL BRAND

Monsol Liquid for dressings, douches, packs, and all sick-room purposes.
Monsol Capsules, keratin-coated, for intestinal disinfection.
Monsol Ointment and *Monsol Throat Pastilles.*

INFANTILE DIARRHOEA

In cases of wasting disorders of early infancy so prevalent at this time of the year, a diet of Mellin's Food in conjunction with cow's milk and water has been found to produce a quicker gain in weight than any other artificial diet.

By the use of

Mellin's Food

for infant feeding these two distinct advantages are secured—

1. There is much less danger of producing digestive disturbances, for Mellin's Food is well tolerated and easily and rapidly assimilated.
2. Where conditions of diarrhoea have been produced by the use of other sugars, the dextro-maltose in Mellin's Food brings the diarrhoea under immediate control.

Further particulars and samples will be supplied on request.

MELLIN'S FOOD LTD., LONDON, S.E.15.

"MODIFIED MILK IN INFANT FEEDING."

Bismostab (BOOTS)

METALLIC BISMUTH SUSPENSION

THE Standard Bismuth Preparation for the treatment of **Syphilis** and other **spirochætal diseases** (Bismuth having largely replaced Mercury as an adjunct to Arsenobenzol Therapy). Bismostab (Boots), a suspension of specially prepared, finely divided, pure Bismuth metal in 5% Glucose solution, is **non-irritant, highly concentrated, sterile and ready for use**

Sold in handy rubber-capped vials containing 5 c.c., 10 c.c. & 1 oz. (28·5 c.c.)

AETHER PURISS. B.D.H.

The cause of the ill-effects which occasionally follow ether anaesthesia was traced, some years ago, directly to impurities in the ether used.

Although the problem of the etiology of ether convulsions remains unsolved, the opinion is still held that impure ether is the chief factor.

The initial manufacture of Aether Puriss. B.D.H. was preceded by exhaustive research on the commercial production of pure ether. As a result, Aether Puriss. B.D.H. is perfectly pure when manufactured, and is bottled under conditions which prevent the formation of peroxides and other toxic decomposition products; in consequence, if kept in its original container until required for use, it remains

"an absolutely pure product"

MEDULLA RUBRA

BONE-MARROW IN ANAEMIA FROM HAEMORRHAGE

W. Borchardt (*Deut. med. Woch.*, March 28th, 1930, p. 521) records the results of his experiments on young dogs in which anaemia had been artificially produced by the removal of about half their blood. In the first series some of the animals were fed with rib-marrow, others with marrow from the long bones. Control animals received a corresponding amount either of fat or of liver extract. The basal diet in each case contained a sufficiency of iron (5 mg. per cent.). Only the animals receiving the rib marrow showed a definite increase of weight, and their haemoglobin formation was more rapid than that of the others. In the next series the experiment was repeated, but the iron content of the diet was reduced to 1.4 mg. per cent. The result was similar but more striking, the dogs receiving the rib marrow regaining their haemoglobin far more quickly than the others.

THIS extract from the "Epitome of Literature," published in the "BRITISH MEDICAL JOURNAL," dated May 3rd last, is important as representing, in 1930, a complete justification of the formula upon which

Roboleine
THE FOOD THAT BUILDS THE BODY.

has been produced without variation during the past twenty-five years.

The success of ROBOLEINE is thus due to intelligent anticipation and to consistently maintaining the highest possible standard of manufacture.

Medical Practitioners are asked to satisfy themselves of the merits of ROBOLEINE, for which purpose testing samples will be gladly sent upon request.

Boots Pure Drug Co. Ltd., Nottingham.

Specially indicated in
NEPHRITIS - URÆMIA - ECLAMPSIA - ALBUMINURIA
and allied conditions.

PROMPT and proper diagnosis of kidney conditions is necessary in cases of Bright's disease and all types of renal disorders. In nine cases out of ten the administration of a specific capable of producing real results in compensating for the loss of kidney function is also necessary.

For more than a quarter of a century Nephritin has been a sheet anchor to physicians in treating such disorders. Nephritin Tablets induce a marked increase in nitrogenous waste elimination. They reactivate the cells of the kidney, increase urinary secretion, and induce a greater output of urea.

Given in sufficient dosage these tablets produce marked results, and restoration to normal is quickly stimulated. They are invaluable also as a prophylactic in renal complications of infectious diseases and during pregnancy. The tablets are composed of the hormones of the normal kidney as they appear in nature—*absolutely unaltered*

'PANOPEPTON'

WHAT IT CONTAINS.

Contains in solution, in an agreeable form, the entire nutritive constituents of beef and wheat.

Contains all that is digestible in beef—in its juice and in its muscle tissues.

Contains all that is digestible in wheat—its gluten, its carbohydrates.

Contains all the savory and stimulating elements, the extractives, the mineral constituents of beef and wheat.

Contains these constituents in the soluble, perfectly diffusible form into which they are converted in the process of normal digestion.

USES OF 'PANOPEPTON.'

Can be relied upon in cases where the nutrition of the patient is of prime importance.

Has saved the patient in desperate straits due to intolerance of food.

Has nourished and restored in many cases where the patient has steadily lost strength on other foods.

Possesses remarkably restorative and stimulating properties.

Is the most nutritious, the most agreeable and reliable—the BEST of all foods for the sick.

For an adult, the usual portion should be a dessertspoonful to a tablespoonful several times a day and at bedtime

SUPPLIED IN 12-oz BOTTLES

OVALTINE

WHEN SLEEP IS DIFFICULT

Judged by the numerous reports received from physicians and also from grateful patients, the use of "Ovaltine" for ensuring sound refreshing sleep deserves the widest recommendation.

It has been remarked that a more helpful prescription could not be wished for because:

1. Taken last thing at night before retiring it exercises a pronounced sedative effect and one that is natural in every sense.
2. It has a pleasantly soothing action on the stomach and nervous system, and does not cause the slightest digestive unrest, or occasion constipation.
3. It promotes a sufficiency of healthful sleep without resourse to hypnotic drugs.

"Ovaltine" is a delicious concentrated extraction of malt, milk, and eggs, in the form of golden granules, which dissolve instantly in milk.

A liberal supply for clinical trial sent free on request.

Local Anæsthesia in Surgical Practice

UTERINE PROLAPSE.

Typical Case.

THIRD DEGREE WITH LARGE VESICOCELE.

Operation: Watkins' interposition: Perineorrhaphy.

Mrs. E. D. F., aged 53.

Anaesthesia: Classical infiltration block, using 40 c.c. of a 0.5 of 1 per cent. Novocain-Adrenaline solution in perineum. A circumferential block about the cervix was made, using 30 c.c. of the same solution. The round ligaments were blocked as soon as they appeared, 4 c.c. of a Novocain-Adrenaline solution being used in each case. The classical Watkins' operation was performed. The perineum was then repaired by the split septum method. Anaesthesia was ideal. Patient's pulse was 80 at end of operation, and she had no post-operative nausea, vomiting, or gas pains, and made an uneventful recovery. —EXTRACT from PRACTICAL LOCAL ANAESTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anaesthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANAESTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Emol-Keleet

Samples free to the Medical Profession on request.

FASSETT & JOHNSON, Ltd.
86, Clerkenwell Road, London, E.C.1.

Beneficial in Inflamed and Irritable Conditions of the Skin.

Emol-Keleet is a natural dusting powder of purely organic origin, combining a marked sedative action with absorbent, emollient and mildly astringent properties. It has a velvety-smooth texture and is remarkably adhesive. Emol-Keleet allays the itching of Eczema and dries up the exudations of "weeping" cases. It relieves the cutaneous irritation accompanying Measles and Scarlet Fever, and soothes any inflammation which may follow vaccination.

Infantile Diarrhoea.

A letter recently received.

The Medical Adviser of
Messrs. Kaylene Ltd.,
London.

Dear Sir,

The case to which I referred was a child of six months who was brought to me after having treatment elsewhere for diarrhoea and vomiting. The child was practically a skeleton and apparently had been vomiting everything—even medicines—for many days. The mother thought, and her friends thought, the child was dying, and I happened to be the nearest doctor. I gave the child one teaspoonful of plain Kaylene in plain, cold, boiled water, and kept the mother and child in my consulting room to watch effects. If ever a child was drawn from the jaws of death, I think that little sufferer was. The Kaylene was retained; the gasping steadily lessened; the haunting look of that child's eyes became less distressing; in fact, the change for the better was so pronounced that in an hour's time I allowed the mother to take the child home.

Fortunately, I had sufficient Kaylene by me (a sample you kindly sent), and I gave the mother sufficient to give a teaspoonful every hour during the night. The chemists' shops were all shut by this time. I gave full instructions—strict instructions—not to give anything else but Kaylene and plain, cold, boiled water as I had done.

In the morning the mother came to see me and informed me that only twice during the night the child had loose stools but no vomiting, and had slept fairly well. The child had other two loose motions during the day, but not offensive ones like all the other stools. In the evening the child cried—the first time for two days—and as she looked, and was, so much better, I gave her some white of egg with plain, cold, boiled water. Still improving, I kept her on this for three days. She was doing well and I then allowed her milk. She made a complete recovery, and there can be no doubt whatever that Kaylene saved the child's life.

Yours faithfully,

..... M.B., C.M.

STANIFORM

Regd. BRAND Trade Mark.

METHYL STANNIC IODIDE

OINTMENT
Immediately stops the pain in all cases of burns, scalds, etc.

DUSTING POWDER
For application where a greasy substance is contra-indicated.

LINIMENT
Remarkably effective in treatment of Rheumatoid Arthritis.

LOTION
A panacea for Mosquito and other insect bites. Most effective for all purposes where Tr. Iodine is employed. Does not stain the skin and there is no sting.

TABLETS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use.

Supplies may be obtained through the Wholesale Druggists, Druggists' Sundriesmen, or Dental Supply Companies.

What the Profession says

The following are some recent unsolicited testimonials reported to the Manufacturers by Medical Men:

"I continue to get every satisfaction from 'Staniform' in the case of carbuncles, boils, whitlows, and all kinds of infected wounds."

"In a case of acute eczema on leg, the skin was quite normal within one week after starting application of 'Staniform Ointment.'"

"Festering wound on left heel when first seen was about the size of a shilling with good deal of pus. Foot much swollen—dressed with 'Staniform Ointment' healed splendidly in four days."

Similar testimony has been received from a large number of medical men when "Staniform" has been used for the treatment of Burns, Wounds, and Skin Ailments.

STANIFORM is used in Leading Hospitals.

STANIFORM over a wide field of clinical experience has exhibited positive curative properties. Combining the well known usefulness of Tin in staphylococcic infections with the powerful germicidal properties of Iodine, Staniform is indicated generally in local inflammations, inducing an immediate soothing effect with rapid healing.

STANIFORM LTD., CARNWATH ROAD, LONDON, S.W.6

Alternative Methods in Prophylaxis and Treatment of

CORYZA

DETOXICATED ANTI-CORYZA VACCINE. This Vaccine has been used with great success for several years. Its outstanding feature is the absence of reaction, which makes it especially useful for hyper-sensitive patients.

ORDINARY ANTI-CORYZA VACCINE. Some Practitioners consider that a slight reaction has definite therapeutic value, and this type of Vaccine has been prepared to meet their requirements. It has the advantage of very low price.

ANTI-CORYZA VACCINE SPRAY (For local application to the nose and throat). For patients who object to Vaccine treatment by subcutaneous injection, and for children, this Local Immunity Product is particularly indicated. An additional convenience is that frequent attendances by the patient for injections are unnecessary.

Additional information regarding the above products will gladly be supplied to any Practitioner who writes to The Vaccine Department, Genatosan Ltd., Loughborough, Leicestershire.

Milk Intolerance.

For many years Benger's Food, as is well known, has been used by practitioners throughout the world as a routine diet in all gastric cases, debility, and in cases of milk intolerance. The reason for this may be briefly stated:—

Benger's Food is a special wheaten flour preparation containing, in suitable amount, the two natural digestive principles — Amylopsin and Trypsin — in a latent state.

It is devised and expressly intended to be used in conjunction with fresh cows' milk, or diluted milk, if desired.

The two enzymes are in such condition as to exert their digestive powers under the condition which obtains during the preparation for use.

The Amylopsin acts on the carbohydrates (Starch) of the Food and gradually changes it into soluble sugars (Dextrins and Maltose mainly, with a little Dextrose) more or less according to the length of time allowed for digestion.

The Trypsin acts on the gluten of the flour and on the proteins (Casein, etc.) of the milk so that the curd which forms is softened, and as a result it separates in the stomach in fine readily-digestible flocculi instead of large, often indigestible curds. The extent of digestion can be varied; *it is important to note that complete pre-digestion can never take place.*

Benger's Food contains no preservatives. It is palatable and is free from rough irritant particles.

These considerations show that Benger's Food is not merely a mechanical milk modifier — it is a real modifier of a peculiar character.

THE "LANCET"
describes it as "Mr. Benger's admirable preparation."

A Physician's sample will be sent post free to any member of the Medical Profession making application to the Proprietors:—
